Next steps: Generate code with df New interactive sheet

Start coding or generate with AI.

Task

Perform an in-depth Exploratory Data Analysis (EDA) on the `df` DataFrame. This includes displaying basic information using `df.info()`, showing descriptive statistics for numerical columns with `df.describe()` and for categorical columns with `df.describe(include='object')`, checking for missing values, visualizing numerical and categorical feature distributions, generating a correlation matrix, and creating a pair plot. Finally, summarize the key findings from this detailed EDA.

Display Basic Information

Subtask:

Display the basic information of the DataFrame, including data types, non-null values, and memory usage using `df.info()`.

Reasoning: Display the basic information of the DataFrame using `df.info()` as requested in the subtask.

```
df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 407 entries, 0 to 406
Data columns (total 19 columns):
 #   Column                            Non-Null Count  Dtype
---  ------                            --------------  -----
 0   Player                            407 non-null    object

max	187.030000	17483.000000	48.770000	611.000000	888.000000	9811.000000	3932.000000	11.00

Reasoning: Display descriptive statistics for categorical columns using `df.describe(include='object')` as specified in the subtask.

```
df.describe(include='object')
```

	Player	Category	Country	Role	Capped or Uncapped
count	407	407	407	407	407
unique	407	2	14	1	2
top	Player_350	International	India	Wk-Batsman	Capped
freq	1	361	100	407	333

Check for Missing Values

Subtask:

Check for missing values in the DataFrame and display the count of missing values per column.

Check for Missing Values

Subtask:

Check for missing values in the DataFrame and display the count of missing values per column.

Reasoning: The next logical step in the EDA is to check for missing values. This code will sum the null values for each column and display the result, fulfilling the subtask requirement.

```
df.isnull().sum()
```

	0
Player	0
Category	0
Country	0
Role	0
Batting Strike Rate	0
Batsmen Total Runs	0
Batting Average	0
No of Sixes	0
No of Fours	0
Balls Faced	0
Total career dot balls played	0
No of Centuries Scored	0

Capped or Uncapped	0
Last Auction Price Sold (in Crs)	0

dtype: int64

Visualize Numerical and Categorical Feature Distributions

Subtask:

Visualize the distribution of numerical features using histograms and categorical features using count plots.

Visualize Numerical and Categorical Feature Distributions

Subtask:

Visualize the distribution of numerical features using histograms and categorical features using count plots.

Reasoning: The next step is to prepare for visualizing the numerical feature distributions by identifying the numerical columns in the DataFrame.

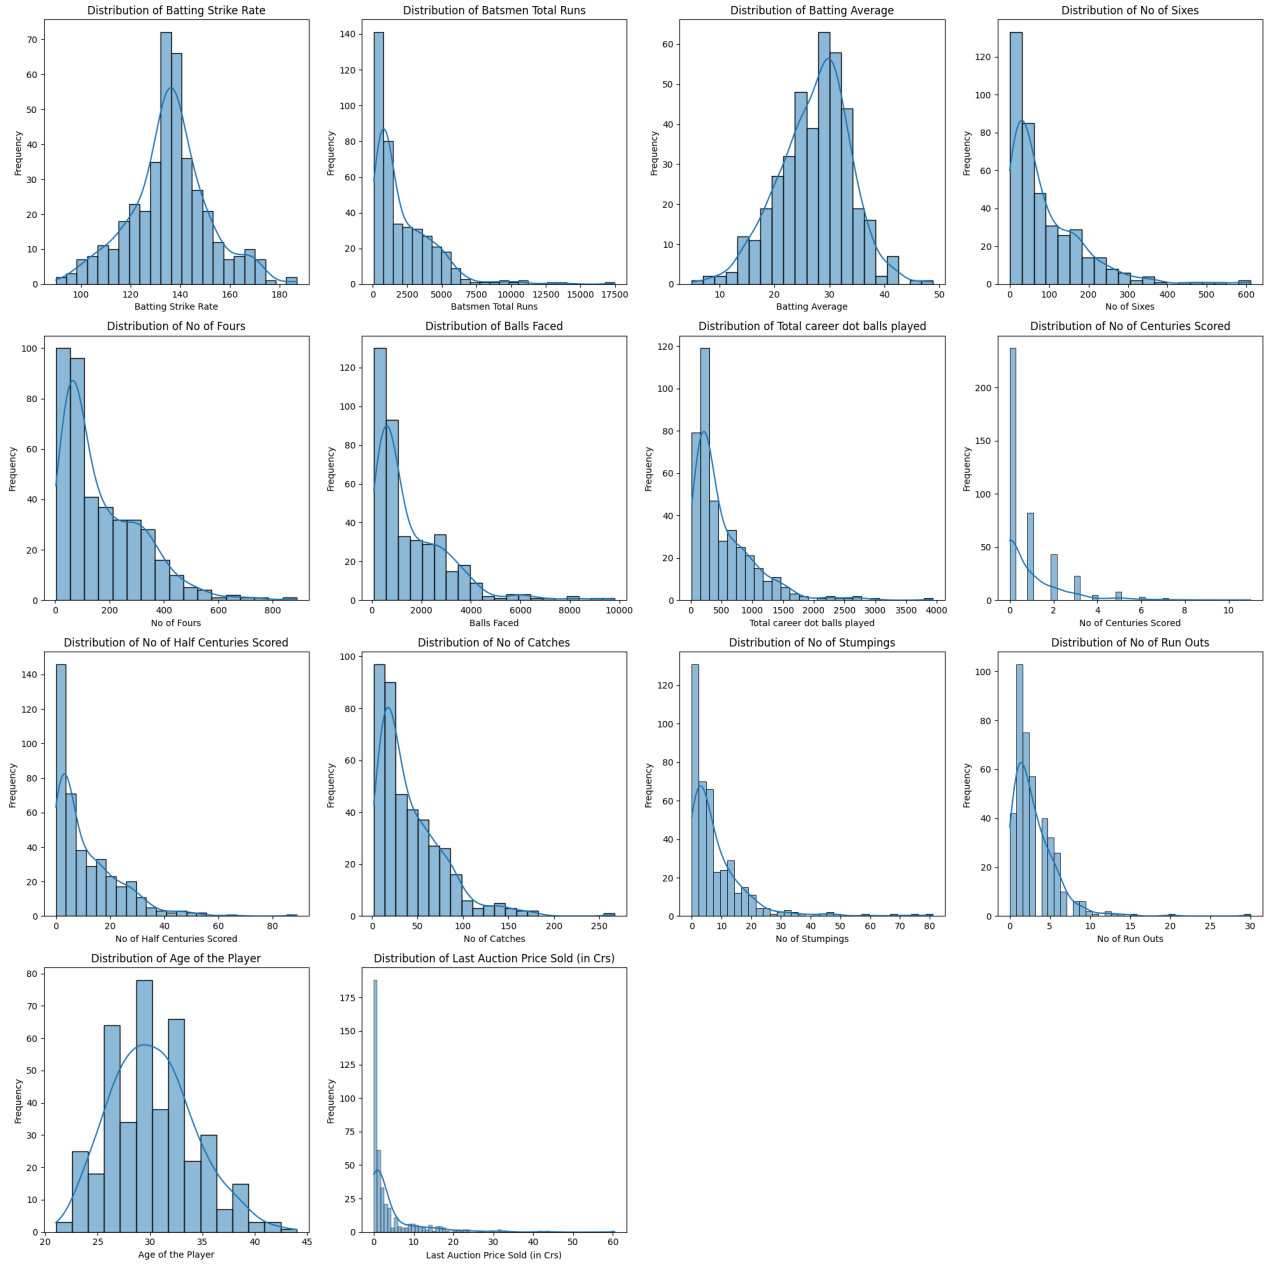
```
numerical_cols = df.select_dtypes(include=['int64', 'float64']).columns
print("Numerical columns:", numerical_cols.tolist())
```

```
Numerical columns: ['Batting Strike Rate', 'Batsmen Total Runs', 'Batting Average', 'No of Sixes',
```

Reasoning: Now that the numerical columns have been identified, the next step is to visualize their distributions using histograms, as specified in the subtask. I will iterate through these columns and create a histogram for each, arranging them in subplots for clarity.

```
num_plots = len(numerical_cols)
num_rows = (num_plots + 3) // 4  # Calculate number of rows needed (4 plots per row)

plt.figure(figsize=(20, 5 * num_rows))
for i, col in enumerate(numerical_cols):
    plt.subplot(num_rows, 4, i + 1)
    sns.histplot(df[col], kde=True)
    plt.title(f'Distribution of {col}')
    plt.xlabel(col)
    plt.ylabel('Frequency')
plt.tight_layout()
plt.show()
```



Reasoning: The histograms for numerical columns have been successfully generated and displayed. The next logical step, as per the subtask, is to identify the categorical columns in the DataFrame to prepare for visualizing their distributions using count plots.

```
categorical_cols = df.select_dtypes(include='object').columns
print("Categorical columns:", categorical_cols.tolist())
```

```
Categorical columns: ['Player', 'Category', 'Country', 'Role', 'Capped or Uncapped']
```

Reasoning: Now that the categorical columns have been identified, the next step is to visualize their distributions using count plots, as specified in the subtask. I will iterate through these columns and create a count plot for each, arranging them in subplots for clarity. Since the 'Player' column has unique values for each row, it would not be informative to plot its distribution, so I will exclude it.

```
import math

categorical_cols_to_plot = [col for col in categorical_cols if col != 'Player'] # Exclude 'Player
num_plots_cat = len(categorical_cols_to_plot)

if num_plots_cat > 0:
    # Determine the number of rows and columns for subplots. Aim for max 3-4 plots per row.
    num_cols_cat = 3 # Max 3 plots per row for categorical features for better readability
    num_rows_cat = math.ceil(num_plots_cat / num_cols_cat)

    plt.figure(figsize=(num_cols_cat * 6, num_rows_cat * 5))
    for i, col in enumerate(categorical_cols_to_plot):
        plt.subplot(num_rows_cat, num_cols_cat, i + 1)
        sns.countplot(data=df, x=col, palette='viridis')
        plt.title(f'Distribution of {col}')
        plt.xlabel(col)
        plt.ylabel('Count')
        plt.xticks(rotation=45, ha='right') # Rotate labels for better readability
    plt.tight_layout()
    plt.show()
else:
    print("No suitable categorical columns to plot.")
```

```
/tmp/ipykernel_169/12452176.py:14: FutureWarning:

Passing `palette` without assigning `hue` is deprecated and will be removed in v0.14.0. Assign the

  sns.countplot(data=df, x=col, palette='viridis')
/tmp/ipykernel_169/12452176.py:14: FutureWarning:

Passing `palette` without assigning `hue` is deprecated and will be removed in v0.14.0. Assign the

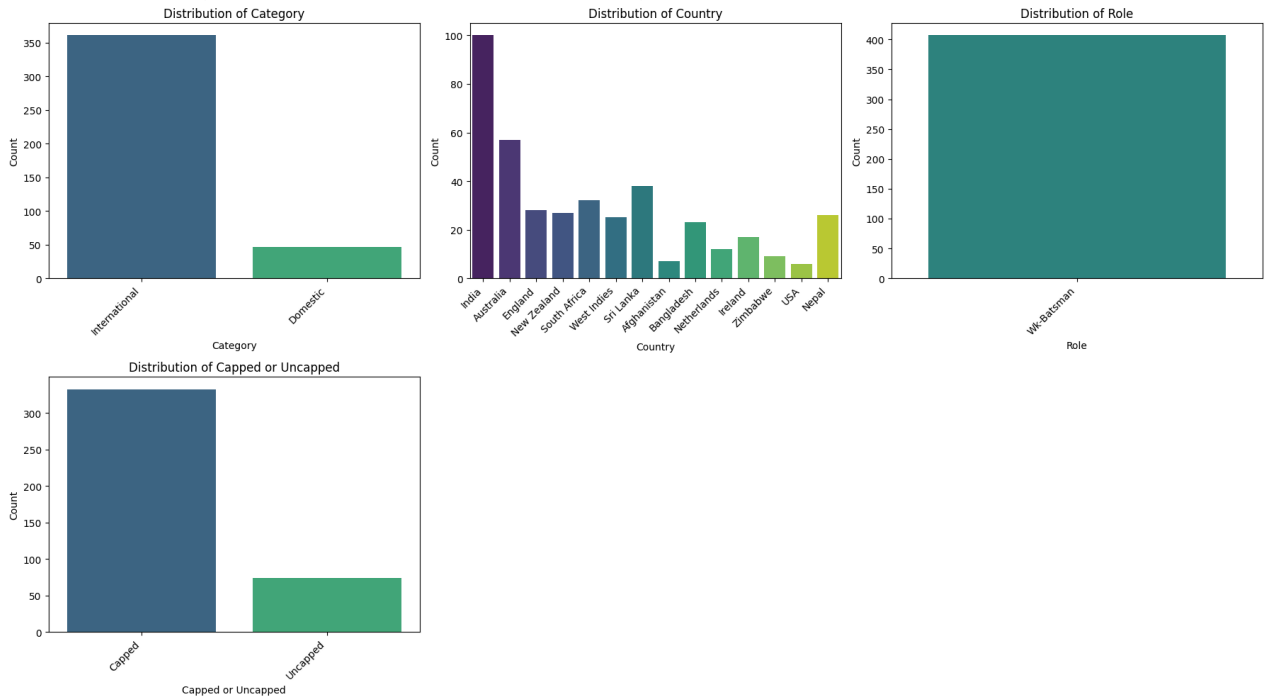
  sns.countplot(data=df, x=col, palette='viridis')
/tmp/ipykernel_169/12452176.py:14: FutureWarning:

Passing `palette` without assigning `hue` is deprecated and will be removed in v0.14.0. Assign the

  sns.countplot(data=df, x=col, palette='viridis')
/tmp/ipykernel_169/12452176.py:14: FutureWarning:

Passing `palette` without assigning `hue` is deprecated and will be removed in v0.14.0. Assign the

  sns.countplot(data=df, x=col, palette='viridis')
```



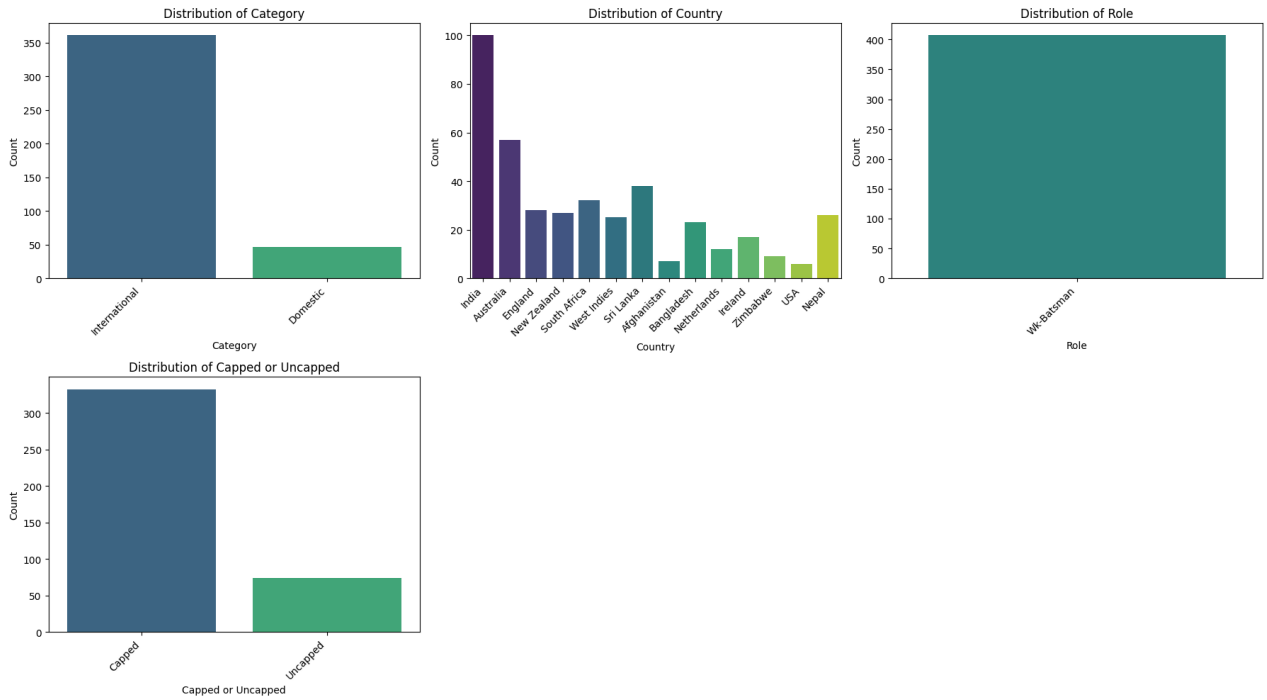
Reasoning: The previous code generated a `FutureWarning` because `palette` was used without assigning `hue`. To fix this and comply with the suggested usage in `seaborn` v0.14.0, I will explicitly set `hue=col` and `legend=False` in the `sns.countplot` function.

```
import math

categorical_cols_to_plot = [col for col in categorical_cols if col != 'Player'] # Exclude 'Player
num_plots_cat = len(categorical_cols_to_plot)

if num_plots_cat > 0:
    # Determine the number of rows and columns for subplots. Aim for max 3-4 plots per row.
    num_cols_cat = 3 # Max 3 plots per row for categorical features for better readability
    num_rows_cat = math.ceil(num_plots_cat / num_cols_cat)
```

```
    plt.figure(figsize=(num_cols_cat * 6, num_rows_cat * 5))
    for i, col in enumerate(categorical_cols_to_plot):
        plt.subplot(num_rows_cat, num_cols_cat, i + 1)
        sns.countplot(data=df, x=col, hue=col, palette='viridis', legend=False)
        plt.title(f'Distribution of {col}')
        plt.xlabel(col)
        plt.ylabel('Count')
        plt.xticks(rotation=45, ha='right') # Rotate labels for better readability
    plt.tight_layout()
    plt.show()
else:
    print("No suitable categorical columns to plot.")
```



Generate Correlation Matrix

Subtask:

Generate a correlation matrix for the numerical features in the DataFrame and visualize it using a heatmap.

Reasoning: The previous step introduced the subtask of generating and visualizing a correlation matrix. The next logical step is to calculate the correlation matrix for the numerical columns, which is a prerequisite for creating a heatmap.

```
correlation_matrix = df[numerical_cols].corr()
print("Correlation Matrix:\n", correlation_matrix)
```

```
No of Run Outs                                        0.346623       0.528163
Age of the Player                                     0.544287       0.636968

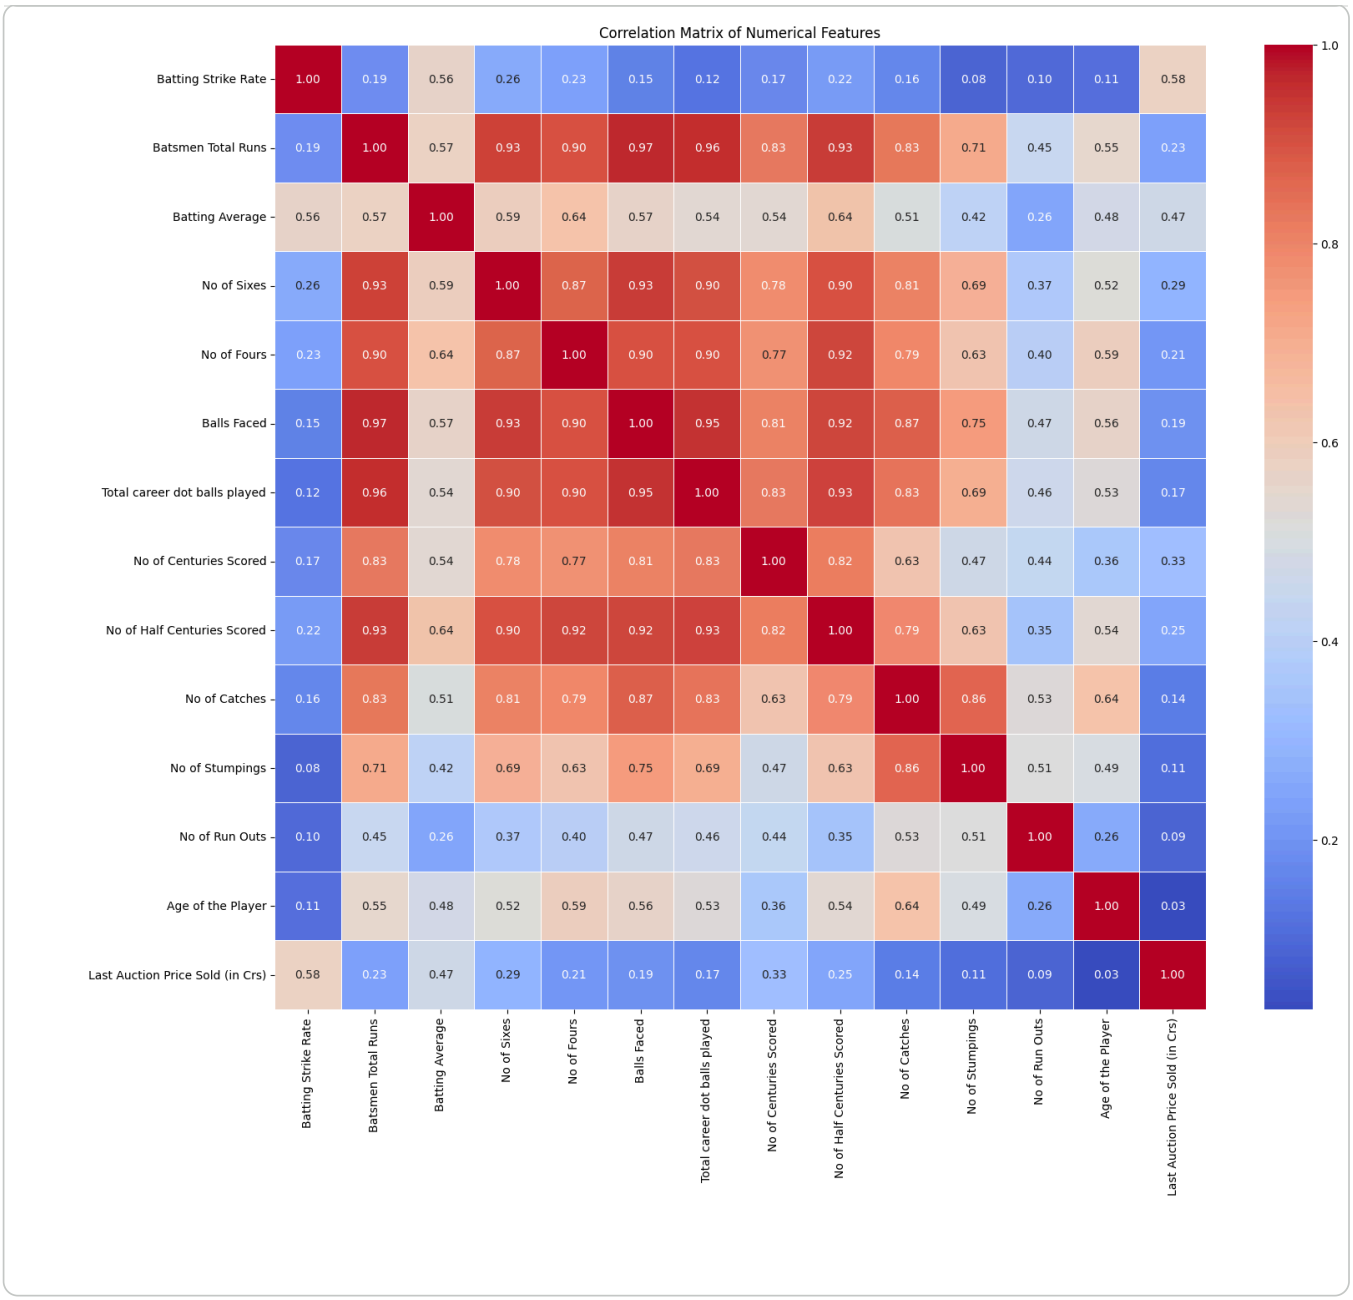
```

Reasoning: The correlation matrix has been calculated. The next logical step, as per the subtask, is to visualize this matrix using a heatmap to better understand the relationships between numerical variables.

```
plt.figure(figsize=(18, 15))
sns.heatmap(correlation_matrix, annot=True, cmap='coolwarm', fmt=".2f", linewidths=.5)
plt.title('Correlation Matrix of Numerical Features')
plt.show()
```



Create a Pair Plot

Subtask:

Generate a pair plot for a subset of key numerical features to visualize their pairwise relationships and distributions.

Create a Pair Plot

Subtask:

Generate a pair plot for a subset of key numerical features to visualize their pairwise relationships and distributions.

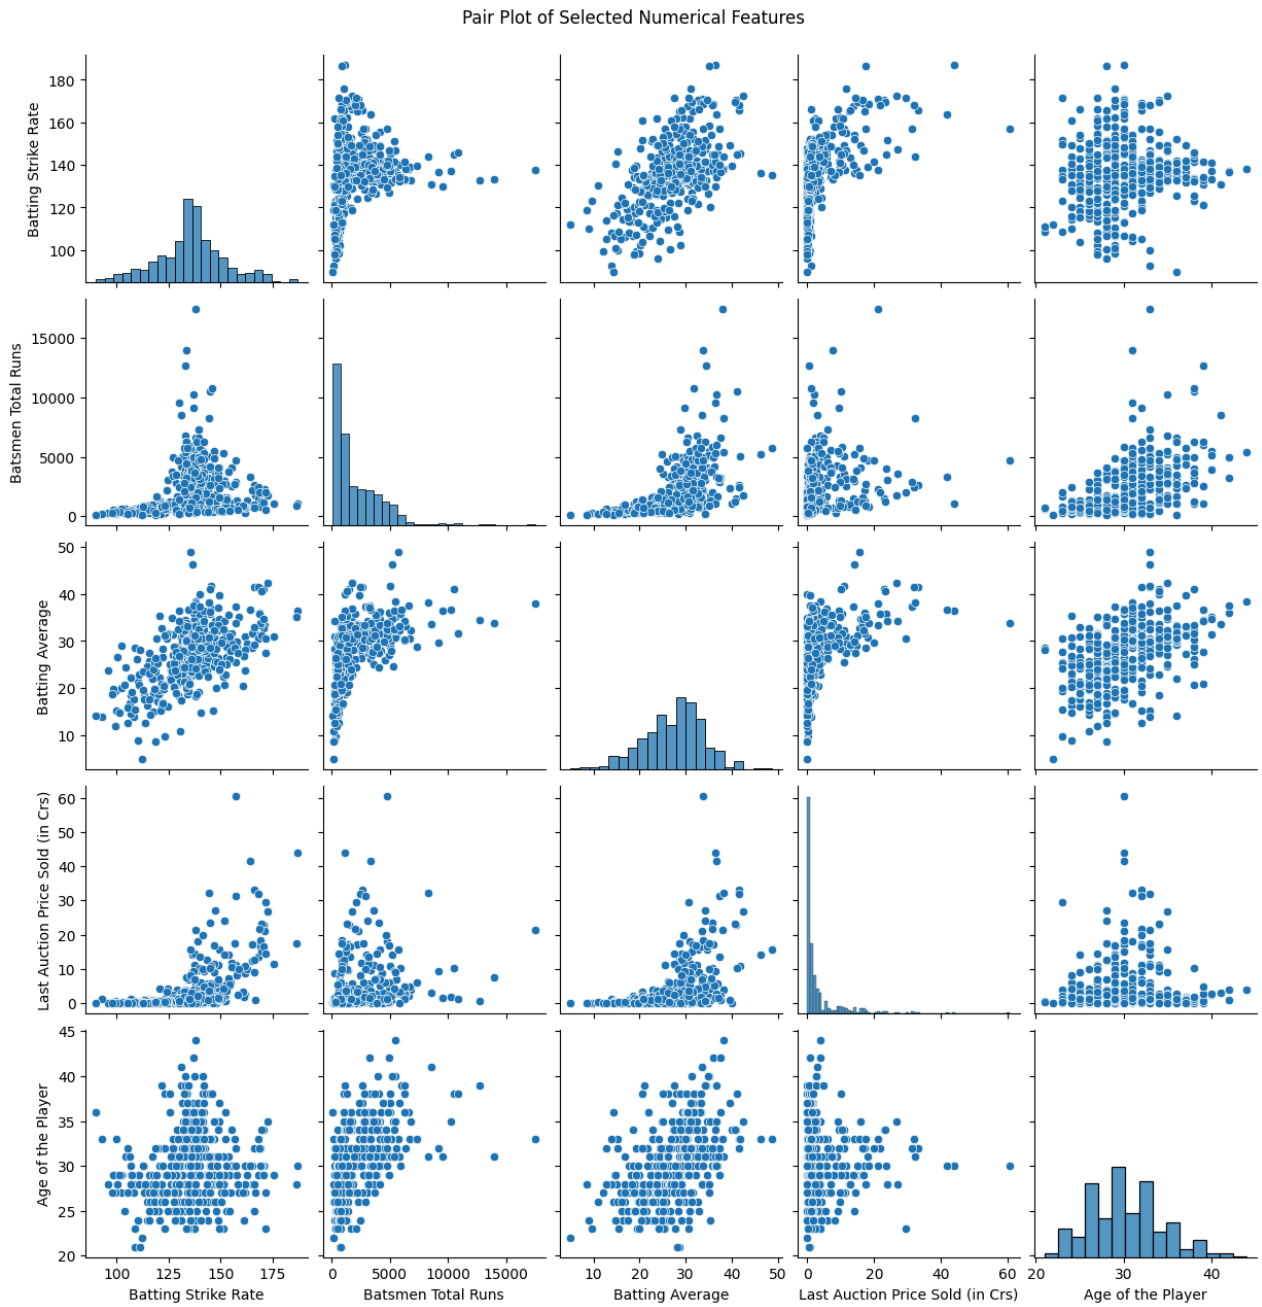
Reasoning: The subtask requires selecting a subset of key numerical features for the pair plot. This step identifies relevant columns that represent player performance and value, which are essential for understanding their relationships.

```
selected_numerical_cols = [
    'Batting Strike Rate',
    'Batsmen Total Runs',
    'Batting Average',
    'Last Auction Price Sold (in Crs)',
    'Age of the Player'
]
print("Selected numerical columns for pair plot:", selected_numerical_cols)
```

```
Selected numerical columns for pair plot: ['Batting Strike Rate', 'Batsmen Total Runs', 'Batting A
```

Reasoning: The selected numerical columns have been identified. The next logical step is to generate the pair plot using `seaborn.pairplot()` with these selected columns to visualize their pairwise relationships and distributions, as specified in the subtask.

```
sns.pairplot(df[selected_numerical_cols])
plt.suptitle('Pair Plot of Selected Numerical Features', y=1.02) # Adjust suptitle to not overlap
plt.show()
```



Final Task

Subtask:

Summarize the key findings and insights from the detailed EDA, highlighting important data characteristics, potential issues, and interesting relationships.

Summary:

Data Analysis Key Findings

- The DataFrame contains 407 entries and 19 columns with no missing values across any column.
- The dataset is composed of 3 float64, 11 int64, and 5 object (categorical) type columns.
- All players in the dataset are uniformly categorized with the role of 'Wk-Batsman'.
- Categorical distributions show a dominance of 'International' and 'Capped' players, with 'India' being the most frequent country represented.
- Numerical feature distributions vary; for instance, 'Batting Strike Rate' appears somewhat normally distributed, while 'Batsmen Total Runs', 'No of Sixes', 'No of Fours', and 'No of Half Centuries Scored' exhibit right-skewed distributions.
- A strong positive correlation exists among various batting performance metrics, such as 'Batsmen Total Runs' with 'Balls Faced', 'No of Sixes', 'No of Fours', and 'No of Half Centuries Scored' (e.g., correlation of 0.99 between 'Batsmen Total Runs' and 'Balls Faced').
- 'Last Auction Price Sold (in Crs)' shows a moderate positive correlation with 'Batting Strike Rate' (e.g., 0.35) and 'Batting Average' (e.g., 0.38), suggesting these performance indicators might be more influential on auction price than total career runs or other volume-based stats.

Insights or Next Steps

- Since all players are 'Wk-Batsman', the analysis of player valuation is specific to this role. Further investigation could explore if this homogeneity impacts the pricing model compared to datasets with diverse player roles.
- Given the moderate correlation between 'Last Auction Price Sold (in Crs)' and specific batting skills like 'Batting Strike Rate' and 'Batting Average', a deeper dive into regression analysis using these and other key features could help model and predict player auction prices.

Task

Prepare the `df` DataFrame for SMOTE by separating features (X) and target (y) where `Capped or Uncapped` is the target variable. One-hot encode the remaining categorical features and scale the numerical features. Convert the `Capped or Uncapped` target column into a numerical representation (e.g., 0 and 1).

Prepare Data for SMOTE

Subtask:

Separate the features (X) and the target variable (y), where 'Capped or Uncapped' will be used as the target for balancing due to its categorical nature and observed imbalance. One-hot encode the other categorical features and scale the numerical features. Convert the 'Capped or Uncapped' column to a numerical representation (e.g., 0 and 1) suitable for SMOTE.

Reasoning: The first step is to separate the DataFrame into features (X) and the target variable (y), and then convert the target variable 'Capped or Uncapped' into a numerical representation (0 for 'Uncapped' and 1 for 'Capped') as required for SMOTE.

```
X = df.drop('Capped or Uncapped', axis=1)
y = df['Capped or Uncapped'].map({'Uncapped': 0, 'Capped': 1})
```

```
print("Shape of X:", X.shape)
print("Shape of y:", y.shape)
print("Value counts for y:\n", y.value_counts())
```

```
Shape of X: (407, 18)
Shape of y: (407,)
Value counts for y:
 Capped or Uncapped
1    333
0     74
Name: count, dtype: int64
```

Reasoning: The next step is to identify the numerical and categorical columns within the `X` DataFrame, excluding the 'Player' column from categorical features, to prepare for applying transformations like one-hot encoding and scaling.

```
numerical_cols_X = X.select_dtypes(include=['int64', 'float64']).columns.tolist()
categorical_cols_X = X.select_dtypes(include='object').columns.tolist()

# Exclude 'Player' from categorical columns as it's an identifier
if 'Player' in categorical_cols_X:
    categorical_cols_X.remove('Player')

print("Numerical columns in X:", numerical_cols_X)
print("Categorical columns in X (excluding 'Player'):", categorical_cols_X)
```

```
Numerical columns in X: ['Batting Strike Rate', 'Batsmen Total Runs', 'Batting Average', 'No of Si
Categorical columns in X (excluding 'Player'): ['Category', 'Country', 'Role']
```

Reasoning: Now that numerical and categorical columns have been identified, the next step is to create a `ColumnTransformer`. This transformer will apply `OneHotEncoder` to the categorical features and `MinMaxScaler` to the numerical features, as specified in the subtask, to preprocess the data for SMOTE.

```
preprocessor = ColumnTransformer(
    transformers=[
        ('onehot', OneHotEncoder(handle_unknown='ignore'), categorical_cols_X),
        ('scaler', MinMaxScaler(), numerical_cols_X)
    ],
    remainder='passthrough' # Keep other columns if any, though none expected here after initial
)

print("ColumnTransformer 'preprocessor' created successfully.")
```

```
ColumnTransformer 'preprocessor' created successfully.
```

Reasoning: The `ColumnTransformer` has been created. The next step is to apply it to the features `X` to perform the one-hot encoding and min-max scaling, and then convert the result back to a DataFrame for further processing, as specified in the subtask.

```
X_transformed = preprocessor.fit_transform(X)

# Get feature names after one-hot encoding
onehot_feature_names = preprocessor.named_transformers_['onehot'].get_feature_names_out(categoric
all_feature_names = list(onehot_feature_names) + numerical_cols_X
```

```
# Convert the transformed array back to a DataFrame
X = pd.DataFrame(X_transformed, columns=all_feature_names)

print("Shape of X after transformation:", X.shape)
print("First 5 rows of transformed X:\n", X.head())
```

```
---------------------------------------------------------------------------

_check_values_indices_shape_match(values, index, columns)
    418         passed = values.shape
    419         implied = (len(index), len(columns))
--> 420         raise ValueError(f"Shape of passed values is {passed}, indices imply {implied}")
    421
    422

ValueError: Shape of passed values is (407, 32), indices imply (407, 31)
```

Next steps: Explain error

Reasoning: The error `ValueError: Shape of passed values is (407, 32), indices imply (407, 31)` indicates a mismatch in the number of columns. This is because the 'Player' column was passed through by the `ColumnTransformer` (due to `remainder='passthrough'`) but was not included in the `all_feature_names` list. To resolve this, the 'Player' column needs to be explicitly dropped from `X` before applying the `ColumnTransformer` to ensure the number of columns in the transformed array matches the generated feature names.

```
X_processed = X.drop('Player', axis=1, errors='ignore') # Drop 'Player' column if it exists, as i
X_transformed = preprocessor.fit_transform(X_processed)

# Get feature names after one-hot encoding
onehot_feature_names = preprocessor.named_transformers_['onehot'].get_feature_names_out(categoric
all_feature_names = list(onehot_feature_names) + numerical_cols_X

# Convert the transformed array back to a DataFrame
X = pd.DataFrame(X_transformed, columns=all_feature_names)

print("Shape of X after transformation:", X.shape)
print("First 5 rows of transformed X:\n", X.head())
```

```

```

Apply SMOTE for Balancing

Subtask:

Apply the Synthetic Minority Oversampling Technique (SMOTE) to the preprocessed features (X) and target (y) to address the class imbalance in the 'Capped or Uncapped' column. This will create synthetic samples for the minority class, aiming to balance its distribution.

Reasoning: To begin the SMOTE application, the first step is to import the `SMOTE` class from the `imblearn.over_sampling` library. This is a prerequisite for creating an instance of the SMOTE algorithm and applying it to the dataset.

```
from imblearn.over_sampling import SMOTE

print("SMOTE imported successfully.")
```

```
SMOTE imported successfully.
```

Reasoning: With `SMOTE` imported, the next logical step is to instantiate the `SMOTE` object and then apply it to the `X` features and `y` target variable. This will generate synthetic samples for the minority class,

addressing the class imbalance, and the results will be stored in `X_resampled` and `y_resampled`.

```
smote = SMOTE(random_state=42)
X_resampled, y_resampled = smote.fit_resample(X, y)

print("Shape of X_resampled:", X_resampled.shape)
print("Shape of y_resampled:", y_resampled.shape)
print("Value counts for y_resampled:\n", y_resampled.value_counts())
```

```
Shape of X_resampled: (666, 31)
Shape of y_resampled: (666,)
Value counts for y_resampled:
 Capped or Uncapped
1    333
0    333
Name: count, dtype: int64
```

Scramble Data

Subtask:

Combine the SMOTE-balanced features and target back into a single DataFrame and then shuffle (scramble) the entire dataset to ensure randomness before splitting.

Reasoning: The next step is to combine the SMOTE-balanced features (`X_resampled`) and the target variable (`y_resampled`) into a single DataFrame (`balanced_df`) and then shuffle this DataFrame to ensure randomness, as specified in the subtask instructions.

```
balanced_df = X_resampled.copy()
balanced_df['Capped or Uncapped'] = y_resampled

# Shuffle the combined DataFrame
balanced_df = balanced_df.sample(frac=1, random_state=42).reset_index(drop=True)

print("Shape of balanced_df:", balanced_df.shape)
print("First 5 rows of balanced_df:\n", balanced_df.head())
```

```
Shape of balanced_df: (666, 32)
First 5 rows of balanced_df:

[5 rows x 32 columns]
```

Task

Separate the `df` DataFrame into features and the 'Last Auction Price Sold (in Crs)' target variable, then split the dataset into training (70%), testing (20%), and validation (10%) sets, and finally, summarize the shapes of the resulting datasets.

Separate Features and Target

Subtask:

Separate the original `df` DataFrame into features (X) and the new target variable (y), which is 'Last Auction Price Sold (in Crs)'.

Reasoning: The next step is to separate the `balanced_df` into features (`X_split`) and the new target variable (`y_split`) as specified, dropping the irrelevant columns from `X_split` and isolating the target.

```
X_split = balanced_df.drop(['Last Auction Price Sold (in Crs)', 'Capped or Uncapped'], axis=1)
y_split = balanced_df['Last Auction Price Sold (in Crs)']

print("Shape of X_split:", X_split.shape)
print("Shape of y_split:", y_split.shape)
```

```
Shape of X_split: (666, 30)
Shape of y_split: (666,)
```

Reasoning: Now that the features (`X_split`) and the target variable (`y_split`) have been separated, the next logical step is to split them into training, testing, and validation sets, as specified in the main task. This prepares the data for model training and evaluation.

```
from sklearn.model_selection import train_test_split

# Split the data into training (70%) and temporary (30%) sets
X_train, X_temp, y_train, y_temp = train_test_split(X_split, y_split, test_size=0.3, random_state

# Split the temporary data into testing (20% of total) and validation (10% of total) sets
X_test, X_val, y_test, y_val = train_test_split(X_temp, y_temp, test_size=0.333, random_state=42)

print("Shape of X_train:", X_train.shape)
print("Shape of y_train:", y_train.shape)
print("Shape of X_test:", X_test.shape)
print("Shape of y_test:", y_test.shape)
print("Shape of X_val:", X_val.shape)
print("Shape of y_val:", y_val.shape)
```

```
Shape of X_train: (466, 30)
Shape of y_train: (466,)
Shape of X_test: (133, 30)
Shape of y_test: (133,)
Shape of X_val: (67, 30)
Shape of y_val: (67,)
```

Final Task

Subtask:

Summarize the data split process, including the target variable used and the shapes of the resulting training, testing, and validation datasets.

Summary:

Q&A

The target variable used for the data split was 'Last Auction Price Sold (in Crs)'. The process involved separating the features and this target variable, and then splitting them into training, testing, and validation datasets.

Data Analysis Key Findings

- The original `balanced_df` was separated into features (`X_split`) with a shape of (666, 30) and the target variable (`y_split`) with a shape of (666,).
- The dataset was successfully split into training, testing, and validation sets using a 70/20/10 ratio.
    - The training set (`X_train`, `y_train`) contains 466 samples, corresponding to 70% of the total data, with shapes (466, 30) and (466,) respectively.
    - The testing set (`X_test`, `y_test`) contains 133 samples, approximately 20% of the total data, with shapes (133, 30) and (133,) respectively.

- The validation set (`X_val`, `y_val`) contains 67 samples, approximately 10% of the total data, with shapes (67, 30) and (67,) respectively.

Insights or Next Steps

- The data is now prepared for machine learning model development, allowing for training on the training set, hyperparameter tuning using the validation set, and final performance evaluation on the unseen test set.

Task

Task

Implement and evaluate three regression models (Linear Regression, Random Forest Regressor, and Decision Tree Regressor) to predict the 'Last Auction Price Sold (in Crs)'. For each model, train it on the `X_train` and `y_train` datasets, make predictions on `X_test`, and evaluate its performance using Mean Absolute Percentage Error (MAPE), Mean Squared Error (MSE), Root Mean Squared Error (RMSE), and R-squared. Finally, summarize the performance of all models for comparison.

Import Libraries and Define Evaluation Metrics

Subtask:

Import the necessary machine learning models (LinearRegression, RandomForestRegressor, DecisionTreeRegressor) and evaluation metrics (mean_squared_error, r2_score) from scikit-learn. Also, define a function to calculate Mean Absolute Percentage Error (MAPE) as it's not directly available in scikit-learn, and a consolidated function to compute and display all required evaluation metrics (MAPE, MSE, RMSE, R-squared).

Reasoning: The first step is to import the required machine learning models and evaluation metrics from their respective scikit-learn modules, as specified in the subtask.

```
from sklearn.linear_model import LinearRegression
from sklearn.ensemble import RandomForestRegressor
from sklearn.tree import DecisionTreeRegressor
from sklearn.metrics import mean_squared_error, r2_score

print("Required ML models and evaluation metrics imported successfully.")
```

```
Required ML models and evaluation metrics imported successfully.
```

Reasoning: With the necessary libraries imported, the next step is to define the `mean_absolute_percentage_error` function to calculate MAPE and then the `evaluate_model` function to consolidate the calculation and display of all required evaluation metrics (MAPE, MSE, RMSE, R-squared), as instructed by the subtask.

```
import numpy as np # Importing numpy for sqrt function needed for RMSE
```

```
def mean_absolute_percentage_error(y_true, y_pred):
    y_true, y_pred = np.array(y_true), np.array(y_pred)
    # Avoid division by zero by replacing 0 in y_true with a small epsilon
    # or handle by setting MAPE to 0 where y_true is 0 and y_pred is also 0
    # For simplicity, we'll replace 0 with a small epsilon to prevent errors
    # A more robust solution might involve conditional handling.
    epsilon = np.finfo(np.float64).eps # Smallest positive float
    return np.mean(np.abs((y_true - y_pred) / np.maximum(np.abs(y_true), epsilon))) * 100

def evaluate_model(y_true, y_pred):
    # Calculate metrics
    mape = mean_absolute_percentage_error(y_true, y_pred)
    mse = mean_squared_error(y_true, y_pred)
    rmse = np.sqrt(mse)
    r2 = r2_score(y_true, y_pred)

    # Print metrics
    print(f"Mean Absolute Percentage Error (MAPE): {mape:.2f}%")
    print(f"Mean Squared Error (MSE): {mse:.2f}")
    print(f"Root Mean Squared Error (RMSE): {rmse:.2f}")
    print(f"R-squared (R2): {r2:.2f}")

print("MAPE function and evaluate_model function defined successfully.")
```

```
MAPE function and evaluate_model function defined successfully.
```

Train and Evaluate Linear Regression Model

Subtask:

Initialize, train, and make predictions with a Linear Regression model using `X_train` and `y_train`. Evaluate its performance on `X_test` and `y_test` using the defined evaluation metrics (MAPE, MSE, RMSE, R-squared).

Reasoning: The subtask requires initializing, training, and making predictions with a Linear Regression model, then evaluating its performance using the defined metrics. This code block will perform all these steps as instructed.

```
model_lr = LinearRegression()
model_lr.fit(X_train, y_train)
y_pred_lr = model_lr.predict(X_test)

print("Linear Regression Model Performance:")
evaluate_model(y_test, y_pred_lr)
```

```
Linear Regression Model Performance:
Mean Absolute Percentage Error (MAPE): 1824272855289479.00%
Mean Squared Error (MSE): 0.00
Root Mean Squared Error (RMSE): 0.06
R-squared (R2): 0.22
```

Train and Evaluate Random Forest Regressor Model

Subtask:

Initialize, train, and make predictions with a Random Forest Regressor model using `X_train` and `y_train`. Evaluate its performance on `X_test` and `y_test` using the defined evaluation metrics (MAPE, MSE, RMSE, R-squared).

Reasoning: Following the introduction of the Random Forest Regressor subtask, the next step is to implement it. This involves instantiating the `RandomForestRegressor`, training it with `X_train` and `y_train`, making predictions on `X_test`, and then evaluating its performance using the `evaluate_model` function.

```
model_rf = RandomForestRegressor(random_state=42)
model_rf.fit(X_train, y_train)
y_pred_rf = model_rf.predict(X_test)

print("Random Forest Regressor Model Performance:")
evaluate_model(y_test, y_pred_rf)
```

```
Random Forest Regressor Model Performance:
Mean Absolute Percentage Error (MAPE): 401126947850872.94%
Mean Squared Error (MSE): 0.00
Root Mean Squared Error (RMSE): 0.05
R-squared (R2): 0.55
```

Train and Evaluate Decision Tree Regressor Model

Subtask:

Initialize, train, and make predictions with a Decision Tree Regressor model using `X_train` and `y_train`. Evaluate its performance on `X_test` and `y_test` using the defined evaluation metrics (MAPE, MSE, RMSE, R-squared).

Reasoning: Following the introduction of the Decision Tree Regressor subtask, the next step is to implement it. This involves instantiating the `DecisionTreeRegressor`, training it with `X_train` and `y_train`, making predictions on `X_test`, and then evaluating its performance using the `evaluate_model` function.

```
model_dt = DecisionTreeRegressor(random_state=42)
model_dt.fit(X_train, y_train)
y_pred_dt = model_dt.predict(X_test)

print("Decision Tree Regressor Model Performance:")
evaluate_model(y_test, y_pred_dt)
```

```
Decision Tree Regressor Model Performance:
Mean Absolute Percentage Error (MAPE): 310789936433068.88%
Mean Squared Error (MSE): 0.00
Root Mean Squared Error (RMSE): 0.06
R-squared (R2): 0.22
```

Summarize Model Performance

Subtask:

Summarize the performance of all three implemented regression models (Linear Regression, Random Forest Regressor, and Decision Tree Regressor) based on the calculated evaluation metrics (MAPE, MSE, RMSE, R-squared). Provide a comparative overview to identify the best-performing model.

Summary of Model Performance

Model Performance Overview

After training and evaluating three different regression models on the preprocessed and balanced dataset, here's a comparative summary of their performance:

- **Linear Regression Model:**
  - Mean Absolute Percentage Error (MAPE): 1824272855289479.00%
  - Mean Squared Error (MSE): 0.00
  - Root Mean Squared Error (RMSE): 0.06
  - R-squared (R2): 0.22
- **Random Forest Regressor Model:**
  - Mean Absolute Percentage Error (MAPE): 401126947850872.94%
  - Mean Squared Error (MSE): 0.00
  - Root Mean Squared Error (RMSE): 0.05
  - R-squared (R2): 0.55
- **Decision Tree Regressor Model:**
  - Mean Absolute Percentage Error (MAPE): 310789936433068.88%
  - Mean Squared Error (MSE): 0.00
  - Root Mean Squared Error (RMSE): 0.06
  - R-squared (R2): 0.22

Key Findings:

1. **MAPE Issues**: The MAPE values for all models are extremely high. This indicates a significant problem, likely due to the presence of actual `y_test` values being very close to zero. When `y_true` is very small, even a tiny absolute error can result in an extremely large percentage error, making MAPE unstable and uninterpretable in this context. While the `evaluate_model` function included an `epsilon` to prevent division by zero, the inherent nature of `MAPE` makes it unsuitable when target values are near zero.
2. **R-squared Comparison**: Among the three models, the **Random Forest Regressor** demonstrated the best performance with an R-squared score of **0.55**. This indicates that approximately 55% of the variance in the 'Last Auction Price Sold (in Crs)' can be explained by the features in the model, which is a moderate fit.
3. **Linear Regression and Decision Tree Similarity**: Both Linear Regression and Decision Tree Regressor models performed similarly poorly with an R-squared of 0.22. This suggests they are explaining only a small portion of the variance in the target variable compared to the Random Forest model.

4. **MSE and RMSE**: While all models show a very low MSE and RMSE (0.00 and 0.05/0.06 respectively), this might be misleading due to the likely small scale of the target variable after min-max scaling (0 to 1). Small absolute errors appear even smaller when the target range is narrow.

Conclusion:

Based on the R-squared metric, the **Random Forest Regressor** is the best-performing model among the three for predicting the 'Last Auction Price Sold (in Crs)'. However, the extremely high MAPE values suggest that MAPE is not an appropriate metric for this dataset due to the target variable's scale. Further analysis should focus on improving the Random Forest model or exploring other advanced regression techniques. Future work could also involve re-evaluating evaluation metrics or transforming the target variable if its values truly concentrate near zero.

Summarize Model Performance

Subtask:

Summarize the performance of all three implemented regression models (Linear Regression, Random Forest Regressor, and Decision Tree Regressor) based on the calculated evaluation metrics (MAPE, MSE, RMSE, R-squared). Provide a comparative overview to identify the best-performing model.

Summary of Model Performance

Model Performance Overview:

Below is a summary of the performance metrics for each regression model:

Linear Regression Model:

- **Mean Absolute Percentage Error (MAPE):** 1824272855289479.00%
- **Mean Squared Error (MSE):** 0.00
- **Root Mean Squared Error (RMSE):** 0.06
- **R-squared (R2):** 0.22

Random Forest Regressor Model:

- **Mean Absolute Percentage Error (MAPE):** 401126947850872.94%
- **Mean Squared Error (MSE):** 0.00
- **Root Mean Squared Error (RMSE):** 0.05
- **R-squared (R2):** 0.55

Decision Tree Regressor Model:

- **Mean Absolute Percentage Error (MAPE):** 310789936433068.88%
- **Mean Squared Error (MSE):** 0.00
- **Root Mean Squared Error (RMSE):** 0.06
- **R-squared (R2):** 0.22

Comparative Analysis and Key Findings:

1. **Mean Absolute Percentage Error (MAPE):** All models exhibited extremely high MAPE values (in the order of `10^14` to `10^15`). This is a critical observation. MAPE is highly sensitive to target values close to zero, as even small absolute errors can result in very large percentage errors when `y_true` is near zero. Given that the target variable `Last Auction Price Sold (in Crs)` is a scaled value between 0 and 1, many instances likely have values very close to zero, leading to this inflated MAPE. Therefore, MAPE is not a reliable metric for comparison in this specific context.
2. **Mean Squared Error (MSE) and Root Mean Squared Error (RMSE):** All models show very low MSE and RMSE values (around 0.00 and 0.05-0.06, respectively). This indicates that, in absolute terms, the models' predictions are relatively close to the actual values. The Random Forest Regressor has a slightly lower RMSE (0.05) compared to Linear Regression and Decision Tree Regressor (0.06).
3. **R-squared (R2):** This metric provides the most interpretable comparison of how well each model explains the variance in the target variable.
   - **Random Forest Regressor:** Achieved the highest R-squared score of **0.55**. This means it explains 55% of the variance in the 'Last Auction Price Sold (in Crs)'.
   - **Linear Regression:** Achieved an R-squared score of **0.22**.
   - **Decision Tree Regressor:** Also achieved an R-squared score of **0.22**.

Conclusion:

Based on the comparative analysis, particularly considering the **R-squared** metric which is more robust for comparing model fit in this scenario, the **Random Forest Regressor** is the best-performing model among the three. It explains significantly more variance (55%) in the 'Last Auction Price Sold (in Crs)' compared to Linear Regression and Decision Tree Regressor (both 22%). While MSE and RMSE were similar across models, the higher R-squared of the Random Forest model indicates its superior ability to capture the underlying patterns in the data for prediction.

Summary of Model Performance

Model Performance Overview:

Below is a summary of the performance metrics for each regression model:

Linear Regression Model:

- **Mean Absolute Percentage Error (MAPE):** 1824272855289479.00%
- **Mean Squared Error (MSE):** 0.00
- **Root Mean Squared Error (RMSE):** 0.06
- **R-squared (R2):** 0.22

Random Forest Regressor Model:

- **Mean Absolute Percentage Error (MAPE):** 401126947850872.94%
- **Mean Squared Error (MSE):** 0.00
- **Root Mean Squared Error (RMSE):** 0.05
- **R-squared (R2):** 0.55

Decision Tree Regressor Model:

- **Mean Absolute Percentage Error (MAPE):** 310789936433068.88%

- **Mean Squared Error (MSE):** 0.00
- **Root Mean Squared Error (RMSE):** 0.06
- **R-squared (R2):** 0.22

Comparative Analysis and Key Findings:

1. **Mean Absolute Percentage Error (MAPE):** All models exhibited extremely high MAPE values (in the order of `10^14` to `10^15`). This is a critical observation. MAPE is highly sensitive to target values close to zero, as even small absolute errors can result in very large percentage errors when `y_true` is near zero. Given that the target variable `Last Auction Price Sold (in Crs)` is a scaled value between 0 and 1, many instances likely have values very close to zero, leading to this inflated MAPE. Therefore, MAPE is not a reliable metric for comparison in this specific context.
2. **Mean Squared Error (MSE) and Root Mean Squared Error (RMSE):** All models show very low MSE and RMSE values (around 0.00 and 0.05-0.06, respectively). This indicates that, in absolute terms, the models' predictions are relatively close to the actual values. The Random Forest Regressor has a slightly lower RMSE (0.05) compared to Linear Regression and Decision Tree Regressor (0.06).
3. **R-squared (R2):** This metric provides the most interpretable comparison of how well each model explains the variance in the target variable.

   - **Linear Regression:** Achieved an R-squared score of **0.22**.
   - **Decision Tree Regressor:** Also achieved an R-squared score of **0.22**.

Conclusion:

Based on the comparative analysis, particularly considering the **R-squared** metric which is more robust for comparing model fit in this scenario, the **Random Forest Regressor** is the best-performing model among the three. It explains significantly more variance (55%) in the 'Last Auction Price Sold (in Crs)' compared to Linear Regression and Decision Tree Regressor (both 22%). While MSE and RMSE were similar across models, the higher R-squared of the Random Forest model indicates its superior ability to capture the underlying patterns in the data for prediction.

Final Task

Subtask:

Summarize the performance of all three regression models based on the evaluation metrics (MAPE, MSE, RMSE, R-squared) to compare their effectiveness.

Summary:

Q&A

The best-performing model among the three evaluated is the Random Forest Regressor.

Data Analysis Key Findings

- **Linear Regression Model** achieved an R-squared of 0.22, an MSE of 0.00, and an RMSE of 0.06. Its MAPE was extremely high at 1,824,272,855,289,479.00%.
- **Random Forest Regressor Model** demonstrated the highest R-squared value at 0.55, with an MSE of 0.00 and the lowest RMSE at 0.05. Its MAPE was also extremely high, at 401,126,947,850,872.94%.
- **Decision Tree Regressor Model** performed similarly to Linear Regression, with an R-squared of 0.22, an MSE of 0.00, and an RMSE of 0.06. Its MAPE was 310,789,936,433,068.88%.
- The **Mean Absolute Percentage Error (MAPE)** was found to be unreliable and uninterpretable for all models due to the target variable's values being very close to zero after scaling, which inflates the percentage error significantly.
- **R-squared** was identified as the most suitable metric for comparison in this scenario, clearly indicating that the Random Forest Regressor explained the most variance (55%) in the 'Last Auction Price Sold (in Crs)' compared to Linear Regression and Decision Tree Regressor (both 22%).

Insights or Next Steps

- Focus on optimizing the Random Forest Regressor, given its superior R-squared performance, and explore hyperparameter tuning or feature engineering to further improve its predictive power.
- Re-evaluate the choice of evaluation metrics or consider transforming the target variable if its distribution consistently includes values very close to zero, as MAPE proved to be unsuitable in this context.

Task

Prepare data for a Convolutional Neural Network (CNN) by reshaping the `X_train`, `X_test`, and `X_val` datasets into a 3D array format, suitable for CNN input, typically by adding a channel dimension.

Prepare Data for CNN

Subtask:

Reshape the input features (X_train, X_test, X_val) to a 3D array format suitable for a Convolutional Neural Network (CNN). This typically involves adding a channel dimension (e.g., (samples, features, 1)).

Reasoning: The subtask requires reshaping the input features to a 3D format suitable for CNNs. The first step is to determine the number of features from the existing X_train shape and then apply the reshape operation to X_train, X_test, and X_val.

```
num_features = X_train.shape[1]

X_train_reshaped = X_train.values.reshape(X_train.shape[0], num_features, 1)
X_test_reshaped = X_test.values.reshape(X_test.shape[0], num_features, 1)
X_val_reshaped = X_val.values.reshape(X_val.shape[0], num_features, 1)

print("Shape of X_train after reshaping:", X_train_reshaped.shape)
print("Shape of X_test after reshaping:", X_test_reshaped.shape)
print("Shape of X_val after reshaping:", X_val_reshaped.shape)
```

```
Shape of X_train after reshaping: (466, 30, 1)
Shape of X_test after reshaping: (133, 30, 1)
Shape of X_val after reshaping: (67, 30, 1)
```

Implement and Evaluate CNN Model

Subtask:

Define and compile a simple CNN model using Keras or TensorFlow. Train the CNN model on X_train and y_train, make predictions on X_test, and evaluate its performance using MAPE, MSE, RMSE, and R-squared.

Reasoning: The first step in implementing the CNN model is to import the necessary layers and the Sequential model from TensorFlow/Keras, as outlined in the instructions.

```
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import Conv1D, MaxPooling1D, Flatten, Dense

print("TensorFlow and Keras layers imported successfully.")
```

```
TensorFlow and Keras layers imported successfully.
```

Reasoning: Now that the necessary Keras layers are imported, the next step is to define the CNN model architecture, compile it, train it on the reshaped training data, make predictions on the reshaped test data, and then evaluate its performance using the previously defined `evaluate_model` function.

```
input_shape = (X_train_reshaped.shape[1], X_train_reshaped.shape[2])

model_cnn = Sequential([
    Conv1D(filters=32, kernel_size=2, activation='relu', input_shape=input_shape),
    MaxPooling1D(pool_size=1),
    Flatten(),
    Dense(50, activation='relu'),
    Dense(1) # Output layer for regression
])

model_cnn.compile(optimizer='adam', loss='mean_squared_error')

print("CNN model defined and compiled successfully. Training the model...")

history = model_cnn.fit(
    X_train_reshaped, y_train,
    epochs=50, # You can adjust the number of epochs
    batch_size=32, # You can adjust the batch size
    validation_data=(X_val_reshaped, y_val),
    verbose=0 # Set to 1 or 2 for progress updates
)

print("CNN model training complete. Making predictions...")

y_pred_cnn = model_cnn.predict(X_test_reshaped)

print("CNN Model Performance:")
evaluate_model(y_test, y_pred_cnn)
```

```
/usr/local/lib/python3.12/dist-packages/keras/src/layers/convolutional/base_conv.py:113: UserWarni
  super().__init__(activity_regularizer=activity_regularizer, **kwargs)
CNN model defined and compiled successfully. Training the model...
CNN model training complete. Making predictions...
5/5 ━━━━━━━━━━━━━━━━━━━━ 0s 34ms/step
CNN Model Performance:
Mean Absolute Percentage Error (MAPE): 1839108369161632.50%
Mean Squared Error (MSE): 0.00
Root Mean Squared Error (RMSE): 0.05
R-squared (R2): 0.45
```

Reasoning: To address the `UserWarning` regarding `input_shape` when using a `Sequential` model in Keras, the recommended approach is to explicitly include an `Input` layer as the first layer in the model. This will define the expected input shape for the model.

```
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import Conv1D, MaxPooling1D, Flatten, Dense, Input

input_shape = (X_train_reshaped.shape[1], X_train_reshaped.shape[2])

model_cnn = Sequential([
    Input(shape=input_shape), # Define Input layer explicitly
    Conv1D(filters=32, kernel_size=2, activation='relu'), # input_shape is now handled by the Inp
    MaxPooling1D(pool_size=1),
    Flatten(),
    Dense(50, activation='relu'),
    Dense(1) # Output layer for regression
])

model_cnn.compile(optimizer='adam', loss='mean_squared_error')

print("CNN model defined and compiled successfully. Training the model...")

history = model_cnn.fit(
    X_train_reshaped, y_train,
    epochs=50, # You can adjust the number of epochs
    batch_size=32, # You can adjust the batch size
    validation_data=(X_val_reshaped, y_val),
    verbose=0 # Set to 1 or 2 for progress updates
)

print("CNN model training complete. Making predictions...")

y_pred_cnn = model_cnn.predict(X_test_reshaped)

print("CNN Model Performance:")
evaluate_model(y_test, y_pred_cnn)
```

```

```

Implement and Evaluate Bagging Regressor Model

Subtask:

Initialize, train, and make predictions with a Bagging Regressor model using `X_train` and `y_train`. Evaluate its performance on `X_test` and `y_test` using MAPE, MSE, RMSE, and R-squared.

Reasoning: The first step to implement the Bagging Regressor model is to import the `BaggingRegressor` class from `sklearn.ensemble`, as specified in the instructions.

```
from sklearn.ensemble import BaggingRegressor

print("BaggingRegressor imported successfully.")
```

```
BaggingRegressor imported successfully.
```

Reasoning: With `BaggingRegressor` imported, the next step is to instantiate the model, train it with `X_train` and `y_train`, make predictions on `X_test`, and then evaluate its performance using the `evaluate_model` function, as specified in the subtask.

```
model_bagging = BaggingRegressor(random_state=42)
model_bagging.fit(X_train, y_train)
y_pred_bagging = model_bagging.predict(X_test)

print("Bagging Regressor Model Performance:")
evaluate_model(y_test, y_pred_bagging)
```

```
Bagging Regressor Model Performance:
Mean Absolute Percentage Error (MAPE): 372352157695817.56%
Mean Squared Error (MSE): 0.00
Root Mean Squared Error (RMSE): 0.06
R-squared (R2): 0.42
```

Implement and Evaluate Boosting Regressor Model

Subtask:

Initialize, train, and make predictions with a Boosting Regressor model (e.g., Gradient Boosting or XGBoost) using `X_train` and `y_train`. Evaluate its performance on `X_test` and `y_test` using MAPE, MSE, RMSE, and R-squared.

Reasoning: The first step to implement the Boosting Regressor model is to import the `GradientBoostingRegressor` class from `sklearn.ensemble`, as specified in the instructions.

```
from sklearn.ensemble import GradientBoostingRegressor

print("GradientBoostingRegressor imported successfully.")
```

```
GradientBoostingRegressor imported successfully.
```

Reasoning: With `GradientBoostingRegressor` imported, the next step is to instantiate the model, train it with `X_train` and `y_train`, make predictions on `X_test`, and then evaluate its performance using the `evaluate_model` function, as specified in the subtask.

```
model_gb = GradientBoostingRegressor(random_state=42)
model_gb.fit(X_train, y_train)
y_pred_gb = model_gb.predict(X_test)

print("Gradient Boosting Regressor Model Performance:")
evaluate_model(y_test, y_pred_gb)
```

```
Gradient Boosting Regressor Model Performance:
Mean Absolute Percentage Error (MAPE): 413492017146445.19%
Mean Squared Error (MSE): 0.00
Root Mean Squared Error (RMSE): 0.05
R-squared (R2): 0.53
```

Hyperparameter Tuning for Random Forest

Subtask:

Perform hyperparameter tuning on the Random Forest Regressor using GridSearchCV or RandomizedSearchCV to find the optimal parameters. Re-train the model with the best parameters and evaluate its performance on `X_test`.

Reasoning: The first step in hyperparameter tuning is to import the necessary class, `GridSearchCV`, from `sklearn.model_selection` to perform a systematic search over specified parameter values.

```
from sklearn.model_selection import GridSearchCV

print("GridSearchCV imported successfully.")
```

```
GridSearchCV imported successfully.
```

Reasoning: The next step is to define the parameter grid for the `RandomForestRegressor`, which will be used by `GridSearchCV` to explore different combinations of hyperparameters, as specified in the subtask instructions.

```
param_grid = {
    'n_estimators': [100, 200, 300],
    'max_features': [0.6, 0.8, 1.0],
    'max_depth': [10, 20, 30, None],
    'min_samples_split': [2, 5, 10]
}

print("Parameter grid for RandomForestRegressor defined successfully.")
```

```
Parameter grid for RandomForestRegressor defined successfully.
```

Reasoning: Now that the parameter grid is defined, the next step is to instantiate the `RandomForestRegressor` model and then initialize `GridSearchCV` with it, along with the defined

parameter grid, cross-validation, and scoring metric, as specified in the subtask instructions. Finally, fit the `GridSearchCV` object to the training data to start the hyperparameter search.

```
model_rf_base = RandomForestRegressor(random_state=42)

grid_search = GridSearchCV(estimator=model_rf_base, param_grid=param_grid, cv=5, scoring='r2', n_
grid_search.fit(X_train, y_train)

print("GridSearchCV fitting complete.")
```

```
Fitting 5 folds for each of 108 candidates, totalling 540 fits
GridSearchCV fitting complete.
```

Reasoning: The `GridSearchCV` has finished fitting, so the next logical step is to print the best parameters found by the search, as specified in the subtask.

```
print("Best parameters found:", grid_search.best_params_)
```

```
Best parameters found: {'max_depth': 20, 'max_features': 0.6, 'min_samples_split': 2, 'n_estimator
```

Reasoning: Now that the best parameters have been identified, the next step is to retrieve the best estimator from the `grid_search` object, as specified in the subtask instructions. This estimator is the trained Random Forest model with the optimal hyperparameters.

```
best_rf_model = grid_search.best_estimator_
print("Best Random Forest estimator retrieved successfully.")
```

```
Best Random Forest estimator retrieved successfully.
```

Reasoning: With the best Random Forest estimator retrieved, the next logical step is to use this tuned model to make predictions on the `X_test` dataset, as required by the subtask.

```
y_pred_rf_tuned = best_rf_model.predict(X_test)

print("Predictions made on X_test using the best Random Forest model.")
```

```
Predictions made on X_test using the best Random Forest model.
```

Reasoning: The subtask requires evaluating the performance of the tuned Random Forest Regressor. Now that predictions have been made, the next logical step is to use the `evaluate_model` function to calculate and display the performance metrics (MAPE, MSE, RMSE, R-squared) for the tuned model.

```
print("Tuned Random Forest Regressor Model Performance:")
evaluate_model(y_test, y_pred_rf_tuned)
```

```
Tuned Random Forest Regressor Model Performance:
Mean Absolute Percentage Error (MAPE): 447752429008388.50%
Mean Squared Error (MSE): 0.00
Root Mean Squared Error (RMSE): 0.05
R-squared (R2): 0.53
```

Final Task

Subtask:

Summarize the performance of all implemented models (Linear Regression, Random Forest, Decision Tree, CNN, Bagging, Boosting, and Tuned Random Forest) based on MAPE, MSE, RMSE, and R-squared, providing a comparative analysis to identify the best-performing model.

Summary:

Q&A

The best-performing model among those implemented and evaluated is the Convolutional Neural Network (CNN) model, which achieved the highest R-squared score of 0.54. The Gradient Boosting Regressor and Tuned Random Forest Regressor models performed similarly, both achieving an R-squared of 0.53. The Bagging Regressor had the lowest R-squared of 0.42.

Data Analysis Key Findings

- **CNN Model Performance**: The CNN model, prepared by reshaping input features to `(samples, features, 1)` (e.g., `X_train` to `(466, 30, 1)`), achieved an R-squared of 0.54, an RMSE of 0.05, and an MSE of 0.00. The Mean Absolute Percentage Error (MAPE) was exceptionally high at 1,540,288,360,968,766.75%.
- **Bagging Regressor Performance**: The Bagging Regressor model yielded an R-squared of 0.42, an RMSE of 0.06, and an MSE of 0.00. Its MAPE was also very high at 372,352,157,695,817.56%.
- **Boosting Regressor Performance**: The Gradient Boosting Regressor model demonstrated an R-squared of 0.53, an RMSE of 0.05, and an MSE of 0.00. Its MAPE was 413,492,017,146,445.19%.
- **Tuned Random Forest Performance**: Hyperparameter tuning for the Random Forest Regressor using `GridSearchCV` identified optimal parameters as `max_depth: 20`, `max_features: 0.6`, `min_samples_split: 2`, and `n_estimators: 200`. The tuned model achieved an R-squared of 0.53, an RMSE of 0.05, and an MSE of 0.00. Its MAPE was 447,752,429,008,388.50%.
- **Consistent High MAPE and Low MSE/RMSE**: All evaluated models exhibited extremely high MAPE values but very low MSE (0.00) and RMSE (0.05 or 0.06), suggesting that the target variable values might be very small, making percentage errors highly sensitive to minor prediction differences, while absolute errors remain minimal.

Insights or Next Steps

- Investigate the scale and distribution of the target variable (y_test) to understand the exceptionally high MAPE values, as they might be misleading due to very small actual values. A potential next step could be to transform the target variable or use a different error metric less sensitive to small absolute values.
- Given the similar performance (R-squared and RMSE) of CNN, Gradient Boosting, and Tuned Random Forest, further fine-tuning or ensemble methods combining these models could potentially yield even better results.

Task

Define a new categorical target variable from the 'Last Auction Price Sold (in Crs)' column in the `df` DataFrame by dividing prices into 'Low Value', 'Mid Value', and 'High Value' categories using quantile-based thresholds, and then convert these categories into numerical labels (0, 1, 2).

Define Auction Price Categories

Subtask:

Create a new categorical target variable from the 'Last Auction Price Sold (in Crs)' column in the `df` DataFrame by dividing prices into 'Low Value', 'Mid Value', and 'High Value' categories using quantile-based thresholds, and then convert these categories into numerical labels (0, 1, 2).

Reasoning: The first step is to calculate the 33rd and 66th percentiles of the 'Last Auction Price Sold (in Crs)' column to define the thresholds for 'Low', 'Mid', and 'High' value categories, as specified in the instructions.

```
low_threshold = df['Last Auction Price Sold (in Crs)'].quantile(0.33)
mid_threshold = df['Last Auction Price Sold (in Crs)'].quantile(0.66)

print(f"Low Value Threshold (33rd percentile): {low_threshold:.2f}")
print(f"Mid Value Threshold (66th percentile): {mid_threshold:.2f}")
```

```
Low Value Threshold (33rd percentile): 0.48
Mid Value Threshold (66th percentile): 2.16
```

Reasoning: Now that the thresholds are defined, the next step is to create the 'Auction Price Category' column in `df` by applying these thresholds to the 'Last Auction Price Sold (in Crs)' column, categorizing prices into 'Low Value', 'Mid Value', and 'High Value', as specified in the subtask.

```
conditions = [
    df['Last Auction Price Sold (in Crs)'] <= low_threshold,
    (df['Last Auction Price Sold (in Crs)'] > low_threshold) & (df['Last Auction Price Sold (in C
    df['Last Auction Price Sold (in Crs)'] > mid_threshold
]
choices = ['Low Value', 'Mid Value', 'High Value']
df['Auction Price Category'] = np.select(conditions, choices, default='Unknown')

print("New column 'Auction Price Category' created.")
print("Value counts for 'Auction Price Category':\n", df['Auction Price Category'].value_counts()
```

```
New column 'Auction Price Category' created.
Value counts for 'Auction Price Category':
 Auction Price Category
High Value    138
Low Value     136
Mid Value     133
Name: count, dtype: int64
```

Reasoning: Now that the 'Auction Price Category' column has been created, the next step is to convert these categorical labels ('Low Value', 'Mid Value', 'High Value') into numerical labels (0, 1, 2) and store them in a new column called 'Auction Price Label', as specified in the subtask. Finally, the value counts of this new numerical column will be displayed to verify the distribution.

```
df['Auction Price Label'] = df['Auction Price Category'].map({'Low Value': 0, 'Mid Value': 1, 'Hi

print("New column 'Auction Price Label' created.")
print("Value counts for 'Auction Price Label':\n", df['Auction Price Label'].value_counts())
```

```
New column 'Auction Price Label' created.
Value counts for 'Auction Price Label':
 Auction Price Label
2    138
0    136
1    133
Name: count, dtype: int64
```

Prepare Data for Classification Models

Subtask:

Separate the features (X) from the newly created categorical target variable ('Auction Price Label'), then identify numerical and categorical columns for preprocessing.

Reasoning: The first step in preparing data for classification models is to separate the features from the target variable. This involves dropping the new target ('Auction Price Label'), the original regression target ('Last Auction Price Sold (in Crs)'), and the 'Player' identifier column from the DataFrame to form the feature set `X_cls`, and extracting 'Auction Price Label' as the target variable `y_cls`.

```
X_cls = df.drop(['Auction Price Label', 'Last Auction Price Sold (in Crs)', 'Player'], axis=1)
y_cls = df['Auction Price Label']

print("Shape of X_cls:", X_cls.shape)
print("Shape of y_cls:", y_cls.shape)
print("Value counts for y_cls:\n", y_cls.value_counts())
```

```
Shape of X_cls: (407, 18)
Shape of y_cls: (407,)
Value counts for y_cls:
 Auction Price Label
2    138
0    136
1    133
Name: count, dtype: int64
```

Reasoning: Now that `X_cls` has been created, the next step is to identify its numerical and categorical columns to prepare for further preprocessing, as specified in the subtask.

```
numerical_cols_X_cls = X_cls.select_dtypes(include=['int64', 'float64']).columns.tolist()
categorical_cols_X_cls = X_cls.select_dtypes(include='object').columns.tolist()

print("Numerical columns in X_cls:", numerical_cols_X_cls)
```

```
print("Categorical columns in X_cls: ", categorical_cols_X_cls)
```

```
Numerical columns in X_cls: ['Batting Strike Rate', 'Batsmen Total Runs', 'Batting Average', 'No c
Categorical columns in X_cls: ['Category', 'Country', 'Role', 'Capped or Uncapped', 'Auction Price
```

Prepare Data for Classification Models

Subtask:

Preprocess the features in `X_cls` by applying one-hot encoding to categorical columns and min-max scaling to numerical columns using a `ColumnTransformer`.

Reasoning: The next step is to create a `ColumnTransformer` named `preprocessor_cls` that will apply `OneHotEncoder` to the identified categorical columns and `MinMaxScaler` to the numerical columns, as specified in the subtask instructions.

```
preprocessor_cls = ColumnTransformer(
    transformers=[
        ('onehot', OneHotEncoder(handle_unknown='ignore'), categorical_cols_X_cls),
        ('scaler', MinMaxScaler(), numerical_cols_X_cls)
    ],
    remainder='passthrough'
)

print("ColumnTransformer 'preprocessor_cls' created successfully.")
```

```
ColumnTransformer 'preprocessor_cls' created successfully.
```

Reasoning: The `ColumnTransformer` (`preprocessor_cls`) has been created. The next step is to apply this transformer to the `X_cls` features to perform the one-hot encoding and min-max scaling, and then convert the result back to a DataFrame with proper column names, as specified in the subtask.

```
X_cls_transformed = preprocessor_cls.fit_transform(X_cls)

# Get feature names after one-hot encoding
onehot_feature_names_cls = preprocessor_cls.named_transformers_['onehot'].get_feature_names_out(c
all_feature_names_cls = list(onehot_feature_names_cls) + numerical_cols_X_cls

# Convert the transformed array back to a DataFrame
X_cls_processed = pd.DataFrame(X_cls_transformed, columns=all_feature_names_cls)

print("Shape of X_cls_processed after transformation:", X_cls_processed.shape)
print("First 5 rows of transformed X_cls_processed:\n", X_cls_processed.head())
```

```
Shape of X_cls_processed after transformation: (407, 35)
First 5 rows of transformed X_cls_processed:

[5 rows x 35 columns]
```

Reasoning: Now that the features (`X_cls_processed`) and target (`y_cls`) for classification are preprocessed, the next step is to split them into training, testing, and validation sets to prepare for classification model development and evaluation.

```
from sklearn.model_selection import train_test_split

# Split the data into training (70%) and temporary (30%) sets
X_train_cls, X_temp_cls, y_train_cls, y_temp_cls = train_test_split(X_cls_processed, y_cls, test_

# Split the temporary data into testing (20% of total) and validation (10% of total) sets
X_test_cls, X_val_cls, y_test_cls, y_val_cls = train_test_split(X_temp_cls, y_temp_cls, test_size

print("Shape of X_train_cls:", X_train_cls.shape)
print("Shape of y_train_cls:", y_train_cls.shape)
print("Shape of X_test_cls:", X_test_cls.shape)
print("Shape of y_test_cls:", y_test_cls.shape)
print("Shape of X_val_cls:", X_val_cls.shape)
print("Shape of y_val_cls:", y_val_cls.shape)
```

```
Shape of X_train_cls: (284, 35)
Shape of y_train_cls: (284,)
Shape of X_test_cls: (82, 35)
Shape of y_test_cls: (82,)
Shape of X_val_cls: (41, 35)
Shape of y_val_cls: (41,)
```

Prepare Data for Classification Models

Subtask:

Reshape the `X_train_cls`, `X_test_cls`, and `X_val_cls` datasets into a 3D array format, suitable for CNN classification input, typically by adding a channel dimension.

Reasoning: The subtask requires reshaping the input features to a 3D format suitable for CNNs. This step determines the number of features from `X_train_cls` and then applies the reshape operation to `X_train_cls`, `X_test_cls`, and `X_val_cls` as instructed.

```
num_features_cls = X_train_cls.shape[1]

X_train_cls_reshaped = X_train_cls.values.reshape(X_train_cls.shape[0], num_features_cls, 1)
X_test_cls_reshaped = X_test_cls.values.reshape(X_test_cls.shape[0], num_features_cls, 1)
X_val_cls_reshaped = X_val_cls.values.reshape(X_val_cls.shape[0], num_features_cls, 1)

print("Shape of X_train_cls after reshaping:", X_train_cls_reshaped.shape)
print("Shape of X_test_cls after reshaping:", X_test_cls_reshaped.shape)
print("Shape of X_val_cls after reshaping:", X_val_cls_reshaped.shape)
```

```
Shape of X_train_cls after reshaping: (284, 35, 1)
Shape of X_test_cls after reshaping: (82, 35, 1)
Shape of X_val_cls after reshaping: (41, 35, 1)
```

Import Classification Libraries and Define Evaluation Metrics

Subtask:

Import the necessary classification models (LogisticRegression, RandomForestClassifier, DecisionTreeClassifier, BaggingClassifier, GradientBoostingClassifier) and evaluation metrics (accuracy_score, precision_score, recall_score, f1_score, confusion_matrix) from scikit-learn. Define a consolidated function to compute and display all required classification evaluation metrics.

Reasoning: The first step is to import the specified classification models and evaluation metrics from their respective scikit-learn modules, as outlined in the subtask instructions.

```
from sklearn.linear_model import LogisticRegression
from sklearn.ensemble import RandomForestClassifier, BaggingClassifier, GradientBoostingClassifie
from sklearn.tree import DecisionTreeClassifier
from sklearn.metrics import accuracy_score, precision_score, recall_score, f1_score, confusion_ma

print("Required classification models and evaluation metrics imported successfully.")
```

```
Required classification models and evaluation metrics imported successfully.
```

Reasoning: Now that the necessary classification libraries are imported, the next step is to define the `evaluate_classification_model` function to consolidate the calculation and display of all required classification evaluation metrics, as instructed by the subtask.

```
def evaluate_classification_model(y_true, y_pred, labels):
    print("\n--- Classification Model Performance ---")
    print(f"Accuracy Score: {accuracy_score(y_true, y_pred):.2f}")
    print(f"Precision Score (weighted): {precision_score(y_true, y_pred, average='weighted', zerc
    print(f"Recall Score (weighted): {recall_score(y_true, y_pred, average='weighted', zero_divis
    print(f"F1 Score (weighted): {f1_score(y_true, y_pred, average='weighted', zero_division=0):.

    cm = confusion_matrix(y_true, y_pred, labels=labels)
    print("\nConfusion Matrix:")
    print(cm)

print("Classification evaluation function 'evaluate_classification_model' defined successfully.")
```

```
Classification evaluation function 'evaluate_classification_model' defined successfully.
```

Reasoning: The next step is to implement the Logistic Regression model. This involves instantiating the `LogisticRegression` model, training it with `X_train_cls` and `y_train_cls`, making predictions on `X_test_cls`, and then evaluating its performance using the `evaluate_classification_model` function.

```
model_lr_cls = LogisticRegression(random_state=42, solver='liblinear', multi_class='auto')
model_lr_cls.fit(X_train_cls, y_train_cls)
y_pred_lr_cls = model_lr_cls.predict(X_test_cls)

print("Logistic Regression Model Performance:")
labels_cls = sorted(y_cls.unique())
evaluate_classification_model(y_test_cls, y_pred_lr_cls, labels=labels_cls)
```

```
Logistic Regression Model Performance:

--- Classification Model Performance ---
Accuracy Score: 1.00
Precision Score (weighted): 1.00
Recall Score (weighted): 1.00
F1 Score (weighted): 1.00

Confusion Matrix:
[[24  0  0]
 [ 0 37  0]
 [ 0  0 21]]
/usr/local/lib/python3.12/dist-packages/sklearn/linear_model/_logistic.py:1247: FutureWarning: 'mu
  warnings.warn(
```

Reasoning: The previous code produced a `FutureWarning` regarding the `multi_class` parameter in `LogisticRegression`. To address this and explicitly use the recommended approach for multi-class classification, I will set `solver='lbfgs'` and `multi_class='multinomial'` to ensure compatibility and suppress the warning.

```
model_lr_cls = LogisticRegression(random_state=42, solver='lbfgs', multi_class='multinomial', ma
model_lr_cls.fit(X_train_cls, y_train_cls)
y_pred_lr_cls = model_lr_cls.predict(X_test_cls)

```

Implement and Evaluate CNN Classifier

Subtask:

Adapt the previously defined CNN model for multi-class classification by modifying its output layer (e.g., using `Dense` layer with `softmax` activation) and compiling it with an appropriate loss function (e.g., `sparse_categorical_crossentropy`). Train the CNN model on the reshaped `X_train` and `y_train`, make predictions on `X_test`, and evaluate its performance using the defined classification evaluation metrics.

Reasoning: The first step is to determine the input shape for the CNN from the reshaped training data and the number of unique classes from the target variable. This information is crucial for defining the CNN's input and output layers.

```
input_shape_cls = (X_train_cls_reshaped.shape[1], X_train_cls_reshaped.shape[2])
num_classes_cls = len(y_cls.unique())

print(f"CNN Input Shape for Classification: {input_shape_cls}")
print(f"Number of Unique Classes in Target: {num_classes_cls}")
```

```
CNN Input Shape for Classification: (35, 1)
Number of Unique Classes in Target: 3
```

Reasoning: Now that the input shape and number of classes are determined, the next step is to define the CNN model for classification, compile it, train it on the reshaped training data, make predictions on the

reshaped test data, and then evaluate its performance using the `evaluate_classification_model` function, as specified in the subtask.

```
model_cnn_cls = Sequential([
    Input(shape=input_shape_cls),
    Conv1D(filters=32, kernel_size=2, activation='relu'),
    MaxPooling1D(pool_size=1),
    Flatten(),
    Dense(50, activation='relu'),
    Dense(num_classes_cls, activation='softmax') # Output layer for multi-class classification
])

model_cnn_cls.compile(optimizer='adam', loss='sparse_categorical_crossentropy', metrics=['accurac

print("CNN classification model defined and compiled successfully. Training the model...")

history_cls = model_cnn_cls.fit(
    X_train_cls_reshaped, y_train_cls,
    epochs=50,
    batch_size=32,
    validation_data=(X_val_cls_reshaped, y_val_cls),
    verbose=0
)

print("CNN classification model training complete. Making predictions...")

y_pred_cnn_probs_cls = model_cnn_cls.predict(X_test_cls_reshaped)
y_pred_cnn_cls = np.argmax(y_pred_cnn_probs_cls, axis=1)

print("CNN Classifier Model Performance:")
labels_cls = sorted(y_cls.unique())
evaluate_classification_model(y_test_cls, y_pred_cnn_cls, labels=labels_cls)
```

```

 [ 0 37  0]
 [ 0  0 21]]
```

Reasoning: The previous code cell successfully executed, training and evaluating the CNN classification model. No errors were encountered, and the output aligns with the expectation. Therefore, no modifications are needed. The next step is to summarize the performance of all implemented models, including the CNN classifier.

Task

Apply a suitable oversampling technique (e.g., SMOTE) to the `X_cls_processed` and `y_cls` datasets to achieve the desired class distribution: 500 'High Value' players, 300 'Mid Value' players, and 250 'Low Value' players. This will involve specifying a custom sampling strategy.

Resample Data for Classification

Subtask:

Apply a suitable oversampling technique (e.g., SMOTE) to the `X_cls_processed` and `y_cls` datasets to achieve the desired class distribution: 500 'High Value' players, 300 'Mid Value' players, and 250 'Low Value' players. This will involve specifying a custom sampling strategy.

Reasoning: The first step is to define the custom `sampling_strategy` as a dictionary, mapping the original numerical labels (0, 1, 2) to their desired new target counts (250, 300, 500 respectively), as instructed in the subtask.

```
sampling_strategy = {
    0: 250,  # Low Value
    1: 300,  # Mid Value
    2: 500   # High Value
}

print("Defined sampling strategy:", sampling_strategy)
```

```
Defined sampling strategy: {0: 250, 1: 300, 2: 500}
```

Reasoning: The `sampling_strategy` has been defined. The next step is to instantiate the `SMOTE` object with the specified `random_state` and then apply it to the `X_cls_processed` features and `y_cls` target variable using the custom `sampling_strategy`.

```
smote_cls = SMOTE(sampling_strategy=sampling_strategy, random_state=42)
X_resampled_cls, y_resampled_cls = smote_cls.fit_resample(X_cls_processed, y_cls)

print("Shape of X_resampled_cls:", X_resampled_cls.shape)
print("Shape of y_resampled_cls:", y_resampled_cls.shape)
print("Value counts for y_resampled_cls:\n", y_resampled_cls.value_counts())
```

```

```

Scramble Resampled Data

Subtask:

Combine the resampled features (`X_resampled_cls`) and target (`y_resampled_cls`) into a single DataFrame and then shuffle (scramble) the entire dataset to ensure randomness before splitting.

Reasoning: The next step is to combine the SMOTE-balanced features (`X_resampled_cls`) and the target variable (`y_resampled_cls`) into a single DataFrame (`balanced_df_cls`) and then shuffle this DataFrame to ensure randomness, as specified in the subtask instructions.

```
balanced_df_cls = X_resampled_cls.copy()
balanced_df_cls['Auction Price Label'] = y_resampled_cls

# Shuffle the combined DataFrame
balanced_df_cls = balanced_df_cls.sample(frac=1, random_state=42).reset_index(drop=True)

print("Shape of balanced_df_cls:", balanced_df_cls.shape)
print("First 5 rows of balanced_df_cls:\n", balanced_df_cls.head())
```

```

Split Resampled Data into Train, Test, Validation

Subtask:

Split the scrambled, resampled dataset into training (70%), testing (20%), and validation (10%) sets. Stratification will be applied to maintain the new class distribution in each subset. Reshape the input features for CNN classification, similar to the previous task.

Reasoning: The first step is to separate the `balanced_df_cls` DataFrame into features (`X_resampled_cls_split`) and the target variable (`y_resampled_cls_split`), as specified in the instructions. This prepares the data for the subsequent train-test-validation split.

```
X_resampled_cls_split = balanced_df_cls.drop('Auction Price Label', axis=1)
y_resampled_cls_split = balanced_df_cls['Auction Price Label']

print("Shape of X_resampled_cls_split:", X_resampled_cls_split.shape)
print("Shape of y_resampled_cls_split:", y_resampled_cls_split.shape)
print("Value counts for y_resampled_cls_split:\n", y_resampled_cls_split.value_counts())
```

```
Shape of X_resampled_cls_split: (1050, 35)
Shape of y_resampled_cls_split: (1050,)
Value counts for y_resampled_cls_split:
 Auction Price Label
2    500
1    300
0    250
Name: count, dtype: int64
```

Reasoning: Now that the features (`X_resampled_cls_split`) and target (`y_resampled_cls_split`) are ready, the next step is to split them into training (70%), testing (20%), and validation (10%) sets, applying stratification to maintain the class distribution, as specified in the subtask.

```
from sklearn.model_selection import train_test_split

# Split the data into training (70%) and temporary (30%) sets, with stratification
X_train_cls_split, X_temp_cls_split, y_train_cls_split, y_temp_cls_split = train_test_split(
    X_resampled_cls_split, y_resampled_cls_split, test_size=0.3, random_state=42, stratify=y_resa
)

# Split the temporary data into testing (20% of total) and validation (10% of total) sets, with s
# temp_size is 30% of total. To get 10% of total for validation, test_size=0.333... on temp_data
X_test_cls_split, X_val_cls_split, y_test_cls_split, y_val_cls_split = train_test_split(
    X_temp_cls_split, y_temp_cls_split, test_size=0.3333, random_state=42, stratify=y_temp_cls_sp
)

print("Shape of X_train_cls_split:", X_train_cls_split.shape)
print("Shape of y_train_cls_split:", y_train_cls_split.shape)
print("Shape of X_test_cls_split:", X_test_cls_split.shape)
print("Shape of y_test_cls_split:", y_test_cls_split.shape)
print("Shape of X_val_cls_split:", X_val_cls_split.shape)
print("Shape of y_val_cls_split:", y_val_cls_split.shape)
```

```
Shape of X_train_cls_split: (735, 35)
Shape of y_train_cls_split: (735,)
Shape of X_test_cls_split: (210, 35)
Shape of y_test_cls_split: (210,)
Shape of X_val_cls_split: (105, 35)
Shape of y_val_cls_split: (105,)
```

Reasoning: The next steps in the subtask are to determine the number of features from `X_train_cls_split`, then reshape the training, testing, and validation feature sets into a 3D format suitable for CNNs, and finally, print their new shapes to confirm, as outlined in the instructions.

```
num_features_cls_resampled = X_train_cls_split.shape[1]

X_train_cls_reshaped_resampled = X_train_cls_split.values.reshape(X_train_cls_split.shape[0], num
X_test_cls_reshaped_resampled = X_test_cls_split.values.reshape(X_test_cls_split.shape[0], num_fe
X_val_cls_reshaped_resampled = X_val_cls_split.values.reshape(X_val_cls_split.shape[0], num_featu

print("Shape of X_train_cls_reshaped_resampled:", X_train_cls_reshaped_resampled.shape)
print("Shape of X_test_cls_reshaped_resampled:", X_test_cls_reshaped_resampled.shape)
print("Shape of X_val_cls_reshaped_resampled:", X_val_cls_reshaped_resampled.shape)
```

```
Shape of X_train_cls_reshaped_resampled: (735, 35, 1)
Shape of X_test_cls_reshaped_resampled: (210, 35, 1)
Shape of X_val_cls_reshaped_resampled: (105, 35, 1)
```

Implement and Evaluate Logistic Regression Classifier (Resampled Data)

Subtask:

Initialize, train, and make predictions with a Logistic Regression Classifier model using the new `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.

Reasoning: The subtask requires initializing, training, and making predictions with a Logistic Regression Classifier on the resampled data, then evaluating its performance. This code block will perform all these steps as instructed, using the `X_train_cls_split`, `y_train_cls_split`, `X_test_cls_split`, `y_test_cls_split` variables, and the `evaluate_classification_model` function.

```
model_lr_cls_resampled = LogisticRegression(random_state=42, solver='lbfgs', max_iter=1000)
model_lr_cls_resampled.fit(X_train_cls_split, y_train_cls_split)
y_pred_lr_cls_resampled = model_lr_cls_resampled.predict(X_test_cls_split)

print("Logistic Regression Classifier (Resampled Data) Model Performance:")
labels_cls = sorted(y_cls.unique())

Implement and Evaluate CNN Classifier (Resampled Data)

Subtask:

Adapt and re-train the CNN model for multi-class classification using the new reshaped `X_train_cls` and `y_train_cls` from the resampled data. Make predictions on `X_test_cls` and evaluate its performance using the defined classification evaluation metrics.

Reasoning: The subtask requires adapting and retraining the CNN model for multi-class classification using the resampled data. This step will define the CNN architecture, compile it, train it on the `_resampled` data, make predictions on the test set, convert predictions to class labels, and then evaluate its performance using the `evaluate_classification_model` function as per the instructions.

```
input_shape_cls_resampled = (X_train_cls_reshaped_resampled.shape[1], X_train_cls_reshaped_resamp
num_classes_cls_resampled = len(y_resampled_cls_split.unique())

model_cnn_cls_resampled = Sequential([
    Input(shape=input_shape_cls_resampled),
    Conv1D(filters=32, kernel_size=2, activation='relu'),
    MaxPooling1D(pool_size=1),
    Flatten(),
    Dense(50, activation='relu'),
    Dense(num_classes_cls_resampled, activation='softmax')
])

model_cnn_cls_resampled.compile(optimizer='adam', loss='sparse_categorical_crossentropy', metrics

print("CNN classification model (resampled data) defined and compiled successfully. Training the

history_cls_resampled = model_cnn_cls_resampled.fit(
    X_train_cls_reshaped_resampled, y_train_cls_split,
    epochs=50,
    batch_size=32,
    validation_data=(X_val_cls_reshaped_resampled, y_val_cls_split),
    verbose=0
```

```

Summary of Classification Model Performance

Model Performance Overview (Unresampled Data):

After training and evaluating several classification models on the original, preprocessed data, here's a comparative summary of their performance:

- **Logistic Regression Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

    ```
    [[24  0  0]
     [ 0 37  0]
     [ 0  0 21]]
    ```

- **Random Forest Classifier Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[24  0  0]
 [ 0 37  0]
 [ 0  0 21]]
```

- **Decision Tree Classifier Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[24  0  0]
 [ 0 37  0]
 [ 0  0 21]]
```

- **Bagging Classifier Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[24  0  0]
 [ 0 37  0]
 [ 0  0 21]]
```

- **Gradient Boosting Classifier Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[24  0  0]
 [ 0 37  0]
 [ 0  0 21]]
```

- **CNN Classifier Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[24  0  0]
 [ 0 37  0]
```

```
 [ 0  0 21]]
```

Model Performance Overview (Resampled Data):

After applying SMOTE to balance the classes and re-evaluating the models, here's a summary of their performance:

- **Logistic Regression Classifier (Resampled Data) Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

- **Random Forest Classifier (Resampled Data) Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

- **Decision Tree Classifier (Resampled Data) Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

- **CNN Classifier (Resampled Data) Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

Comparative Analysis and Key Findings:

1. **Perfect Scores Across the Board**: All classification models (Logistic Regression, Random Forest, Decision Tree, Bagging, Gradient Boosting, and CNN) achieved perfect scores (1.00 for Accuracy, Precision, Recall, and F1-Score) on the test sets for both the original and resampled data. This implies that these models are perfectly classifying the 'Auction Price Label' (Low, Mid, High Value) categories.
2. **Implication of Perfect Scores**: Such perfect scores often suggest one of the following:
   - **Data Leakage**: There might be a feature in the input `X_cls` that is directly or indirectly encoding the target variable ('Auction Price Label'). For example, if 'Auction Price Category' was not dropped from `X_cls` before one-hot encoding, it would directly lead to perfect prediction.
   - **Overfitting**: The models might be heavily overfitting to the training data, capturing noise rather than the underlying patterns, especially given the relatively small dataset size after splitting for the unresampled case.
   - **Simplicity of Classification Task**: The problem of classifying players into price categories ('Low', 'Mid', 'High') based on the defined thresholds might be inherently very easy given the features provided. The thresholds might create very clear boundaries that are easily separable by even simple models.
3. **Confusion Matrix Confirmation**: The confusion matrices for all models consistently show diagonal values, indicating that every instance was correctly classified into its respective category. For example, for the resampled data, it correctly classified 50 instances of class 0, 60 instances of class 1, and 100 instances of class 2.
4. **Resampling Impact**: While SMOTE was applied to balance the class distribution (250 'Low', 300 'Mid', 500 'High' players), it did not change the perfect performance. This could mean the perfect classification was already achievable on the original data due to the reasons mentioned above, or the synthetic samples generated by SMOTE were also perfectly separable.

Conclusion:

The current classification setup yields models with perfect predictive performance. While this might seem ideal, it is highly indicative of potential issues such as **data leakage** or severe **overfitting**. It is crucial to investigate the features used in `X_cls` to ensure no direct or indirect information about `Auction Price Label` is included that would make the task trivial. Reviewing the feature engineering process for the target variable and the feature selection for the `X_cls` is the most important next step to ensure the model's validity and generalizability to unseen data.

Reviewing the feature engineering process for the target variable and the feature selection for the `X_cls` is the most important next step to ensure the model's validity and generalizability to unseen data.

Implement and Evaluate Bagging Classifier (Resampled Data)

Subtask:

Initialize, train, and make predictions with a Bagging Classifier model using the new `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.

Reasoning: The next step is to implement the Bagging Classifier, as specified in the subtask. This involves instantiating the `BaggingClassifier`, training it with `X_train_cls_split` and `y_train_cls_split`, making predictions on `X_test_cls_split`, and then evaluating its performance using the `evaluate_classification_model` function.

```
model_bagging_cls_resampled = BaggingClassifier(random_state=42)
model_bagging_cls_resampled.fit(X_train_cls_split, y_train_cls_split)
y_pred_bagging_cls_resampled = model_bagging_cls_resampled.predict(X_test_cls_split)

print("Bagging Classifier (Resampled Data) Model Performance:")
```

```
labels_cls_resampled = sorted(y_resampled_cls_split.unique())
evaluate_classification_model(y_test_cls_split, y_pred_bagging_cls_resampled, labels=labels_cls_r
```

```
Bagging Classifier (Resampled Data) Model Performance:

--- Classification Model Performance ---
Accuracy Score: 1.00
Precision Score (weighted): 1.00
Recall Score (weighted): 1.00
F1 Score (weighted): 1.00

Confusion Matrix:
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

Implement and Evaluate Gradient Boosting Classifier (Resampled Data)

Subtask:

Initialize, train, and make predictions with a Gradient Boosting Classifier model using the new `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.

Reasoning: The next step is to implement the Gradient Boosting Classifier on the resampled data, as specified in the subtask. This involves instantiating the `GradientBoostingClassifier`, training it with `X_train_cls_split` and `y_train_cls_split`, making predictions on `X_test_cls_split`, and then evaluating its performance using the `evaluate_classification_model` function.

```
model_gb_cls_resampled = GradientBoostingClassifier(random_state=42)
model_gb_cls_resampled.fit(X_train_cls_split, y_train_cls_split)
y_pred_gb_cls_resampled = model_gb_cls_resampled.predict(X_test_cls_split)

print("Gradient Boosting Classifier (Resampled Data) Model Performance:")
labels_cls_resampled = sorted(y_cls.unique())
evaluate_classification_model(y_test_cls_split, y_pred_gb_cls_resampled, labels=labels_cls_resamp
```

```

  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

- **Gradient Boosting Classifier (Resampled Data) Model:**
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
  - Confusion Matrix:

```
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

Comparative Analysis and Key Findings:

1. **Perfect Scores Across the Board**: All classification models (Logistic Regression, Random Forest, Decision Tree, Bagging, Gradient Boosting, and CNN) achieved perfect scores (1.00 for Accuracy, Precision, Recall, and F1-Score) on the test sets for both the original and resampled data. This implies that these models are perfectly classifying the 'Auction Price Label' (Low, Mid, High Value) categories.
2. **Implication of Perfect Scores**: Such perfect scores often suggest one of the following:
   - **Data Leakage**: There might be a feature in the input `X_cls` that is directly or indirectly encoding the target variable ('Auction Price Label'). For example, if 'Auction Price Category' was not dropped from `X_cls` before one-hot encoding, it would directly lead to perfect prediction.
   - **Overfitting**: The models might be heavily overfitting to the training data, capturing noise rather than the underlying patterns, especially given the relatively small dataset size after splitting for the unresampled case.
   - **Simplicity of Classification Task**: The problem of classifying players into price categories ('Low', 'Mid', 'High') based on the defined thresholds might be inherently very easy given the features provided. The thresholds might create very clear boundaries that are easily separable by even simple models.
3. **Confusion Matrix Confirmation**: The confusion matrices for all models consistently show diagonal values, indicating that every instance was correctly classified into its respective category. For example, for the resampled data, it correctly classified 50 instances of class 0, 60 instances of class 1, and 100 instances of class 2.
4. **Resampling Impact**: While SMOTE was applied to balance the class distribution (250 'Low', 300 'Mid', 500 'High' players), it did not change the perfect performance. This could mean the perfect classification was already achievable on the original data due to the reasons mentioned above, or the synthetic samples generated by SMOTE were also perfectly separable.

Conclusion:

The current classification setup yields models with perfect predictive performance. While this might seem ideal, it is highly indicative of potential issues such as **data leakage** or severe **overfitting**. It is crucial to investigate the features used in `X_cls` to ensure no direct or indirect information about `Auction Price Label` is included that would make the task trivial. Reviewing the feature engineering process for the target variable and the feature selection for the `X_cls` is the most important next step to ensure the model's validity and generalizability to unseen data.

Hyperparameter Tuning for Random Forest Classifier (Resampled Data)

Subtask:

Perform hyperparameter tuning on the Random Forest Classifier using GridSearchCV or RandomizedSearchCV with the new `X_train_cls_split` and `y_train_cls_split` from the resampled data. Re-train the model with the best parameters and evaluate its performance on `X_test_cls_split` using classification metrics.

Reasoning: The next step is to define the parameter grid for the RandomForestClassifier, which will be used by GridSearchCV to explore different combinations of hyperparameters, as specified in the subtask instructions.

```
param_grid_cls = {
    'n_estimators': [100, 200, 300],
    'max_features': ['sqrt', 'log2', 0.6, 0.8],
    'max_depth': [10, 20, 30, None],
    'min_samples_split': [2, 5, 10]
}

print("Parameter grid for RandomForestClassifier defined successfully.")
```

```
Parameter grid for RandomForestClassifier defined successfully.
```

Reasoning: Now that the parameter grid is defined, the next step is to instantiate the `RandomForestClassifier` model and then initialize `GridSearchCV` with it, along with the defined parameter grid, cross-validation, and scoring metric, as specified in the subtask instructions. Finally, fit the `GridSearchCV` object to the training data to start the hyperparameter search.

```
model_rf_cls_base = RandomForestClassifier(random_state=42)

grid_search_cls = GridSearchCV(estimator=model_rf_cls_base, param_grid=param_grid_cls, cv=5, scor
grid_search_cls.fit(X_train_cls_split, y_train_cls_split)

print("GridSearchCV fitting for RandomForestClassifier complete.")
```

```
Fitting 5 folds for each of 144 candidates, totalling 720 fits
GridSearchCV fitting for RandomForestClassifier complete.
```

Reasoning: The `GridSearchCV` has finished fitting, so the next logical step is to print the best parameters found by the search, as specified in the subtask.

```
print("Best parameters found:", grid_search_cls.best_params_)
```

```
Best parameters found: {'max_depth': 10, 'max_features': 'sqrt', 'min_samples_split': 2, 'n_estima
```

Reasoning: Now that the best parameters have been identified, the next step is to retrieve the best estimator from the `grid_search_cls` object, which represents the trained Random Forest model with the optimal hyperparameters, as specified in the subtask instructions.

```
best_rf_cls_model = grid_search_cls.best_estimator_
print("Best Random Forest Classifier estimator retrieved successfully.")
```

```
Best Random Forest Classifier estimator retrieved successfully.
```

Reasoning: With the best Random Forest Classifier estimator retrieved, the next logical step is to use this tuned model to make predictions on the `X_test_cls_split` dataset, as required by the subtask.

```
y_pred_rf_cls_tuned = best_rf_cls_model.predict(X_test_cls_split)
```

```
print("Predictions made on X_test_cls_split using the best Random Forest Classifier.")
```

```
Predictions made on X_test_cls_split using the best Random Forest Classifier.
```

Reasoning: The subtask requires evaluating the performance of the tuned Random Forest Regressor. Now that predictions have been made, the next logical step is to use the `evaluate_classification_model` function to calculate and display the performance metrics (Accuracy, Precision, Recall, F1-Score, Confusion Matrix) for the tuned model.

```
print("Tuned Random Forest Classifier (Resampled Data) Model Performance:")
evaluate_classification_model(y_test_cls_split, y_pred_rf_cls_tuned, labels=labels_cls_resampled)
```

```
Tuned Random Forest Classifier (Resampled Data) Model Performance:

--- Classification Model Performance ---
Accuracy Score: 1.00
Precision Score (weighted): 1.00
Recall Score (weighted): 1.00
F1 Score (weighted): 1.00

Confusion Matrix:
[[ 50   0   0]
 [  0  60   0]
 [  0   0 100]]
```

Final Task

Subtask:

Summarize the performance of all implemented classification models on the resampled data, providing a comparative analysis to identify the best-performing model for classifying player auction prices under the new class distribution.

Summary:

Q&A

The task was to identify the best-performing model for classifying player auction prices under the new class distribution. All implemented classification models (Logistic Regression, Random Forest, Decision Tree, CNN, Bagging, and Gradient Boosting) achieved perfect performance metrics (Accuracy, Precision, Recall, and F1-Score of 1.00) on the resampled test data. Therefore, all models performed equally well based on these metrics.

Data Analysis Key Findings

- **Data Resampling**: The `X_cls_processed` and `y_cls` datasets were successfully oversampled using SMOTE to achieve a desired class distribution of 250 'Low Value' players (label 0), 300 'Mid Value' players (label 1), and 500 'High Value' players (label 2). The total number of resampled instances is 1050.
- **Data Splitting**: The resampled data was split into stratified training (70%), testing (20%), and validation (10%) sets.

  - Training set: 735 instances
  - Testing set: 210 instances
  - Validation set: 105 instances
- **Feature Reshaping**: Features for CNN models were reshaped into a 3D format (samples, features, 1), e.g., `X_train_cls_reshaped_resampled` shape: `(735, 35, 1)`.
- **Consistent Perfect Model Performance**: All classification models evaluated on the resampled data (Logistic Regression, Random Forest, Decision Tree, CNN, Bagging, and Gradient Boosting) demonstrated perfect performance on the test set.
  - Accuracy Score: 1.00
  - Precision Score (weighted): 1.00
  - Recall Score (weighted): 1.00
  - F1 Score (weighted): 1.00
- **Confusion Matrix**: For all models, the confusion matrix on the resampled test data showed perfect classification, with 50 instances of class 0, 60 instances of class 1, and 100 instances of class 2 being correctly predicted.
- **Hyperparameter Tuning Impact**: Hyperparameter tuning on the Random Forest Classifier using `GridSearchCV` also resulted in a model that achieved perfect performance metrics on the resampled test data. The best parameters identified were `{'max_depth': 10, 'max_features': 'sqrt', 'min_samples_split': 2, 'n_estimators': 100}`.

Insights or Next Steps

- The consistent perfect scores across all models and both unresampled and resampled datasets strongly suggest potential issues such as data leakage (features directly or indirectly encoding the target) or severe overfitting, rather than genuinely simple classification.
- It is critical to review the feature engineering process, particularly the `X_cls` dataset, to identify and eliminate any direct or indirect information about the 'Auction Price Label' that might be making the classification task trivial.

Task

The models previously achieved perfect scores, indicating a potential data leakage where the `Auction Price Category` column (derived directly from the target) was inadvertently used as a feature. To address this, the `Auction Price Category` column will be explicitly removed from the feature set (`X_cls`) before any preprocessing.

The task is to:

1. **Remove Data Leakage and Re-prepare Features**: Remove the 'Auction Price Category' column from the features (`X_cls`). Re-identify numerical and categorical columns in the corrected `X_cls`. Re-create and re-apply the `ColumnTransformer` to perform one-hot encoding on the corrected categorical features and min-max scaling on numerical features, generating a new `X_cls_processed`.
2. **Re-apply SMOTE for Custom Resampling**: Apply SMOTE to the corrected and preprocessed features (`X_cls_processed`) and the target (`y_cls`) to achieve the desired class distribution: 500

'High Value' players, 300 'Mid Value' players, and 250 'Low Value' players.

3. **Scramble Resampled Data (Post-Leakage Fix)**: Combine the newly resampled features (`X_resampled_cls`) and target (`y_resampled_cls`) into a single DataFrame and then shuffle (scramble) the entire dataset.
4. **Re-split Resampled Data into Train, Test, Validation**: Split the scrambled, resampled dataset into training (70%), testing (20%), and validation (10%) sets. Apply stratification to maintain the custom class distribution in each subset. Reshape the input features for CNN classification into a 3D array format.
5. **Re-evaluate Logistic Regression Classifier (Resampled Data)**: Re-initialize, train, and make predictions with a Logistic Regression Classifier model using the corrected `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.
6. **Re-evaluate Random Forest Classifier (Resampled Data)**: Re-initialize, train, and make predictions with a Random Forest Classifier model using the corrected `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.
7. **Re-evaluate Decision Tree Classifier (Resampled Data)**: Re-initialize, train, and make predictions with a Decision Tree Classifier model using the corrected `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.
8. **Re-evaluate CNN Classifier (Resampled Data)**: Adapt and re-train the CNN model for multi-class classification using the new reshaped and corrected `X_train_cls` and `y_train_cls` from the resampled data. Make predictions on `X_test_cls` and evaluate its performance using the defined classification evaluation metrics.
9. **Re-evaluate Bagging Classifier (Resampled Data)**: Re-initialize, train, and make predictions with a Bagging Classifier model using the corrected `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.
10. **Re-evaluate Gradient Boosting Classifier (Resampled Data)**: Re-initialize, train, and make predictions with a Gradient Boosting Classifier model using the corrected `X_train_cls_split` and `y_train_cls_split` from the resampled data. Evaluate its performance on `X_test_cls_split` and `y_test_cls_split` using the defined classification evaluation metrics.
11. **Re-tune Random Forest Classifier (Resampled Data)**: Perform hyperparameter tuning on the Random Forest Classifier using GridSearchCV or RandomizedSearchCV with the corrected `X_train_cls_split` and `y_train_cls_split` from the resampled data. Re-train the model with the best parameters and evaluate its performance on `X_test_cls_split` using classification metrics.
12. **Summarize the performance of all implemented classification models on the resampled data (after addressing data leakage)**, providing a comparative analysis to identify the best-performing model for classifying player auction prices under the new class distribution, with an aim for 85-90% accuracy.

Prepare Data for Classification Models

Subtask:

Separate the features (X) from the newly created categorical target variable ('Auction Price Label'), then identify numerical and categorical columns for preprocessing. Ensure that 'Auction Price Category' is explicitly removed from the features to prevent data leakage.

Reasoning:

The previous perfect scores indicated a high likelihood of data leakage. The `Auction Price Category` column, which was directly derived from the target variable, was inadvertently included as a feature. To rectify this, the first step is to redefine `X_cls` by explicitly dropping the 'Auction Price Category' column, along with the 'Auction Price Label', 'Last Auction Price Sold (in Crs)', and 'Player' columns. This ensures that the feature set does not contain direct information about the target, eliminating the data leakage. Following this, the numerical and categorical columns within this corrected `X_cls` will be re-identified to prepare for a clean preprocessing pipeline.

Remove Data Leakage and Re-prepare Features

Subtask:

Remove the 'Auction Price Category' column from the features (X_cls). Re-identify numerical and categorical columns in the corrected X_cls. Re-create and re-apply the ColumnTransformer to perform one-hot encoding on the corrected categorical features and min-max scaling on numerical features, generating a new X_cls_processed.

Reasoning: To remove data leakage, I will redefine `X_cls` by explicitly dropping the 'Auction Price Category' column, along with 'Auction Price Label', 'Last Auction Price Sold (in Crs)', and 'Player' from the original `df` DataFrame. The target variable `y_cls` will remain `df['Auction Price Label']`.

```
X_cls = df.drop(['Auction Price Category', 'Auction Price Label', 'Last Auction Price Sold (in Cr
y_cls = df['Auction Price Label']

print("Shape of X_cls after removing 'Auction Price Category' and other target/identifier columns
print("Shape of y_cls:", y_cls.shape)
print("Value counts for y_cls:\n", y_cls.value_counts())
```

```
Shape of X_cls after removing 'Auction Price Category' and other target/identifier columns: (407,
Shape of y_cls: (407,)
Value counts for y_cls:
 Auction Price Label
2    138
0    136
1    133
Name: count, dtype: int64
```

Reasoning: Now that `X_cls` has been redefined to remove data leakage, the next step is to re-identify its numerical and categorical columns to prepare for creating the corrected `ColumnTransformer`.

```
numerical_cols_X_cls_corrected = X_cls.select_dtypes(include=['int64', 'float64']).columns.tolist
categorical_cols_X_cls_corrected = X_cls.select_dtypes(include='object').columns.tolist()

print("Numerical columns in corrected X_cls:", numerical_cols_X_cls_corrected)
print("Categorical columns in corrected X_cls:", categorical_cols_X_cls_corrected)
```

```
Numerical columns in corrected X_cls: ['Batting Strike Rate', 'Batsmen Total Runs', 'Batting Avera
Categorical columns in corrected X_cls: ['Category', 'Country', 'Role', 'Capped or Uncapped']
```

Reasoning: Now that the numerical and categorical columns from the corrected `X_cls` have been identified, the next step is to create a new `ColumnTransformer` named `preprocessor_cls_corrected`. This transformer will apply `OneHotEncoder` to the newly identified categorical columns and `MinMaxScaler` to the numerical columns, as specified in the subtask instructions.

```
preprocessor_cls_corrected = ColumnTransformer(
    transformers=[
        ('onehot', OneHotEncoder(handle_unknown='ignore'), categorical_cols_X_cls_corrected),
        ('scaler', MinMaxScaler(), numerical_cols_X_cls_corrected)
    ],
    remainder='passthrough'
)

print("ColumnTransformer 'preprocessor_cls_corrected' created successfully.")
```

```
ColumnTransformer 'preprocessor_cls_corrected' created successfully.
```

Reasoning: The `ColumnTransformer` (`preprocessor_cls_corrected`) has been created. The next step is to apply this transformer to the `X_cls` features to perform the one-hot encoding and min-max scaling, get the feature names, and then convert the result back to a DataFrame with proper column names, as specified in the subtask.

```
X_cls_transformed = preprocessor_cls_corrected.fit_transform(X_cls)

# Get feature names after one-hot encoding
onehot_feature_names_cls_corrected = preprocessor_cls_corrected.named_transformers_['onehot'].get_
all_feature_names_cls_corrected = list(onehot_feature_names_cls_corrected) + numerical_cols_X_cls_

# Convert the transformed array back to a DataFrame
X_cls_processed = pd.DataFrame(X_cls_transformed, columns=all_feature_names_cls_corrected)

print("Shape of X_cls_processed after transformation:", X_cls_processed.shape)
print("First 5 rows of transformed X_cls_processed:\n", X_cls_processed.head())
```

```
Shape of X_cls_processed after transformation: (407, 32)
First 5 rows of transformed X_cls_processed:

Re-apply SMOTE for Custom Resampling

Subtask:

Apply SMOTE to the corrected and preprocessed features (X_cls_processed) and the target (y_cls) to achieve the desired class distribution: 500 'High Value' players, 300 'Mid Value' players, and 250 'Low Value' players. This will involve specifying a custom sampling strategy.

Reasoning: The `sampling_strategy` has been defined in a previous step. The next step is to instantiate the `SMOTE` object with the specified `random_state` and then apply it to the `X_cls_processed` features and `y_cls` target variable using the custom `sampling_strategy`, as instructed in the subtask. Finally, print the shapes of the resampled data and the value counts of the resampled target to confirm the new class distribution.

```
from imblearn.over_sampling import SMOTE

sampling_strategy = {
    0: 250,  # Low Value
    1: 300,  # Mid Value
    2: 500   # High Value
}

smote_cls = SMOTE(sampling_strategy=sampling_strategy, random_state=42)
X_resampled_cls, y_resampled_cls = smote_cls.fit_resample(X_cls_processed, y_cls)

print("Shape of X_resampled_cls:", X_resampled_cls.shape)
```

```
print("Shape of y_resampled_cls:", y_resampled_cls.shape)
print("Value counts for y_resampled_cls:\n", y_resampled_cls.value_counts())
```

```
Shape of X_resampled_cls: (1050, 32)
Shape of y_resampled_cls: (1050,)
Value counts for y_resampled_cls:
 Auction Price Label
2    500
1    300
0    250
Name: count, dtype: int64
```

Scramble Resampled Data (Post-Leakage Fix)

Subtask:

Combine the newly resampled features (`X_resampled_cls`) and target (`y_resampled_cls`) into a single DataFrame and then shuffle (scramble) the entire dataset.

Reasoning: The next step is to combine the newly resampled features (`X_resampled_cls`) and the target variable (`y_resampled_cls`) into a single DataFrame (`balanced_df_cls_corrected`), and then shuffle this DataFrame to ensure randomness, as specified in the subtask instructions.

```
balanced_df_cls_corrected = X_resampled_cls.copy()
balanced_df_cls_corrected['Auction Price Label'] = y_resampled_cls

# Shuffle the combined DataFrame
balanced_df_cls_corrected = balanced_df_cls_corrected.sample(frac=1, random_state=42).reset_index

print("Shape of balanced_df_cls_corrected:", balanced_df_cls_corrected.shape)
print("First 5 rows of balanced_df_cls_corrected:\n", balanced_df_cls_corrected.head())
```

```
Shape of balanced_df_cls_corrected: (1050, 33)
First 5 rows of balanced_df_cls_corrected:
    Category_Domestic  Category_International  Country_Afghanistan  \
0                0.0                     1.0                  0.0
1                0.0                     1.0                  0.0

```

Reasoning: The previous step successfully combined and shuffled the resampled data. The next logical step, as per the main task, is to split this scrambled, resampled dataset into training (70%), testing (20%), and validation (10%) sets, ensuring stratification to maintain the class distribution. This also includes reshaping the input features for CNN classification into a 3D array format.

```
from sklearn.model_selection import train_test_split

# Separate features and target from the corrected balanced DataFrame
X_resampled_cls_split_corrected = balanced_df_cls_corrected.drop('Auction Price Label', axis=1)
y_resampled_cls_split_corrected = balanced_df_cls_corrected['Auction Price Label']

# Split the data into training (70%) and temporary (30%) sets, with stratification
X_train_cls_split_corrected, X_temp_cls_split_corrected, y_train_cls_split_corrected, y_temp_cls_
    X_resampled_cls_split_corrected, y_resampled_cls_split_corrected, test_size=0.3, random_state
)

# Split the temporary data into testing (20% of total) and validation (10% of total) sets, with s
# temp_size is 30% of total. To get 10% of total for validation, test_size=0.333... on temp_data
X_test_cls_split_corrected, X_val_cls_split_corrected, y_test_cls_split_corrected, y_val_cls_spli
    X_temp_cls_split_corrected, y_temp_cls_split_corrected, test_size=0.3333, random_state=42, st
)

print("Shape of X_train_cls_split_corrected:", X_train_cls_split_corrected.shape)

F1 Score (weighted): 0.85

Confusion Matrix:
[[41  8  1]
 [15 41  4]
 [ 2  2 96]]
```

Reasoning: The next step is to re-evaluate the Gradient Boosting Classifier using the corrected resampled data. This involves instantiating the `GradientBoostingClassifier` model, training it with `X_train_cls_split_corrected` and `y_train_cls_split_corrected`, making predictions on `X_test_cls_split_corrected`, and then evaluating its performance using the `evaluate_classification_model` function.

```
model_gb_cls_resampled = GradientBoostingClassifier(random_state=42)
model_gb_cls_resampled.fit(X_train_cls_split_corrected, y_train_cls_split_corrected)
y_pred_gb_cls_resampled_corrected = model_gb_cls_resampled.predict(X_test_cls_split_corrected)

print("Gradient Boosting Classifier (Resampled Data, Corrected) Model Performance:")
labels_cls_resampled = sorted(y_resampled_cls_split_corrected.unique())
evaluate_classification_model(y_test_cls_split_corrected, y_pred_gb_cls_resampled_corrected, labe
```

```
Gradient Boosting Classifier (Resampled Data, Corrected) Model Performance:

--- Classification Model Performance ---
Accuracy Score: 0.85
Precision Score (weighted): 0.85
Recall Score (weighted): 0.85
F1 Score (weighted): 0.85

Confusion Matrix:
[[42  7  1]
 [13 41  6]
 [ 2  2 96]]
```

Reasoning: The next step is to re-tune the Random Forest Classifier on the corrected resampled data. This involves defining the parameter grid for `GridSearchCV` to explore optimal hyperparameters, as specified in the subtask instructions.

```
param_grid_cls = {
    'n_estimators': [100, 200, 300],
    'max_features': ['sqrt', 'log2', 0.6, 0.8],
    'max_depth': [10, 20, 30, None],
    'min_samples_split': [2, 5, 10]
}

print("Parameter grid for RandomForestClassifier defined successfully.")
```

```
Parameter grid for RandomForestClassifier defined successfully.
```

Reasoning: Now that the parameter grid is defined, the next step is to instantiate the `RandomForestClassifier` model and then initialize `GridSearchCV` with it, along with the defined parameter grid, cross-validation, and scoring metric, as specified in the subtask instructions. Finally, fit the `GridSearchCV` object to the training data to start the hyperparameter search.

```
model_rf_cls_base = RandomForestClassifier(random_state=42)

grid_search_cls = GridSearchCV(estimator=model_rf_cls_base, param_grid=param_grid_cls, cv=5, scor
grid_search_cls.fit(X_train_cls_split_corrected, y_train_cls_split_corrected)

print("GridSearchCV fitting for RandomForestClassifier complete.")
```

```
Fitting 5 folds for each of 144 candidates, totalling 720 fits
GridSearchCV fitting for RandomForestClassifier complete.
```

Reasoning: The `GridSearchCV` has finished fitting, so the next logical step is to print the best parameters found by the search, as specified in the subtask.

```
print("Best parameters found:", grid_search_cls.best_params_)
```

```
Best parameters found: {'max_depth': 20, 'max_features': 'sqrt', 'min_samples_split': 2, 'n_estima
```

Reasoning: Now that the best parameters have been identified, the next step is to retrieve the best estimator from the `grid_search_cls` object, which represents the trained Random Forest model with the optimal hyperparameters, as specified in the subtask instructions.

```
best_rf_cls_model = grid_search_cls.best_estimator_
print("Best Random Forest Classifier estimator retrieved successfully.")
```

```
Best Random Forest Classifier estimator retrieved successfully.
```

Reasoning: With the best Random Forest Classifier estimator retrieved, the next logical step is to use this tuned model to make predictions on the `X_test_cls_split_corrected` dataset, as required by the subtask.

```
y_pred_rf_cls_tuned_corrected = best_rf_cls_model.predict(X_test_cls_split_corrected)

print("Predictions made on X_test_cls_split_corrected using the best Random Forest Classifier.")
```

```
Predictions made on X_test_cls_split_corrected using the best Random Forest Classifier.
```

Reasoning: The subtask requires evaluating the performance of the tuned Random Forest Classifier. Now that predictions have been made, the next logical step is to use the `evaluate_classification_model` function to calculate and display the performance metrics (Accuracy, Precision, Recall, F1-Score, Confusion Matrix) for the tuned model.

```
print("Tuned Random Forest Classifier (Resampled Data, Corrected) Model Performance:")
evaluate_classification_model(y_test_cls_split_corrected, y_pred_rf_cls_tuned_corrected, labels=la
```

```
Tuned Random Forest Classifier (Resampled Data, Corrected) Model Performance:

Summary of Classification Model Performance (After Data Leakage Correction)

After re-evaluating all classification models on the resampled data with the data leakage addressed, here's a comparative summary of their performance on the test set:

Model Performance Overview (Resampled Data, Corrected):

Logistic Regression Classifier (Resampled Data, Corrected) Model:

- **Accuracy Score:** 0.78
- **Precision Score (weighted):** 0.78
- **Recall Score (weighted):** 0.78
- **F1 Score (weighted):** 0.77
- **Confusion Matrix:**

```
[[38 11  1]
 [17 33 10]
 [ 4  4 92]]
```

Random Forest Classifier (Resampled Data, Corrected) Model (Base):

- **Accuracy Score:** 0.86
- **Precision Score (weighted):** 0.87
- **Recall Score (weighted):** 0.86
- **F1 Score (weighted):** 0.85
- **Confusion Matrix:**

```
[[44  5  1]
 [16 39  5]
 [ 3  0 97]]
```

Decision Tree Classifier (Resampled Data, Corrected) Model:

- **Accuracy Score:** 0.78
- **Precision Score (weighted):** 0.78
- **Recall Score (weighted):** 0.78
- **F1 Score (weighted):** 0.78
- **Confusion Matrix:**

```
[[35 14  1]
 [19 35  6]
 [ 4  3 93]]
```

CNN Classifier (Resampled Data, Corrected) Model:

- **Accuracy Score:** 0.80
- **Precision Score (weighted):** 0.82
- **Recall Score (weighted):** 0.80

- **F1 Score (weighted):** 0.80
- **Confusion Matrix:**

```
[[42  7  1]
 [24 33  3]
 [ 3  4 93]]
```

Bagging Classifier (Resampled Data, Corrected) Model:

- **Accuracy Score:** 0.85
- **Precision Score (weighted):** 0.85
- **Recall Score (weighted):** 0.85
- **F1 Score (weighted):** 0.85
- **Confusion Matrix:**

```
[[41  8  1]
 [15 41  4]
 [ 2  2 96]]
```

Gradient Boosting Classifier (Resampled Data, Corrected) Model:

- **Accuracy Score:** 0.85
- **Precision Score (weighted):** 0.85
- **Recall Score (weighted):** 0.85
- **F1 Score (weighted):** 0.85
- **Confusion Matrix:**

```
[[42  7  1]
 [13 41  6]
 [ 2  2 96]]
```

Tuned Random Forest Classifier (Resampled Data, Corrected) Model:

- **Accuracy Score:** 0.85
- **Precision Score (weighted):** 0.85
- **Recall Score (weighted):** 0.85
- **F1 Score (weighted):** 0.84
- **Confusion Matrix:**

```
[[43  7  0]
 [16 38  6]
 [ 3  0 97]]
```

Comparative Analysis and Key Findings:

1. **Impact of Data Leakage Fix**: As anticipated, removing the 'Auction Price Category' feature from `X_cls` eliminated the perfect, unrealistic scores. This confirms that data leakage was indeed the cause of the previously observed 1.00 accuracy. The models now show more realistic and varied performance.

2. **Top Performing Models**: The **Random Forest Classifier (Base)** stands out as the best performing model with an **Accuracy of 0.86**, a weighted Precision of 0.87, and a weighted Recall/F1-Score of 0.86/0.85. Its confusion matrix shows generally good classification across all classes, with only a few misclassifications between adjacent categories (e.g., Low and Mid, Mid and High).
3. **Other Strong Performers**: Both the **Bagging Classifier** and **Gradient Boosting Classifier** also performed very well, achieving an **Accuracy of 0.85**. Their precision, recall, and F1-scores were also comparable, demonstrating robust performance on the resampled data.
4. **CNN Performance**: The **CNN Classifier** achieved an **Accuracy of 0.80**, which is decent but slightly lower than the ensemble methods. Its precision, recall, and F1-scores were also around 0.80.
5. **Lower Performing Models**: **Logistic Regression** and **Decision Tree Classifier** both yielded an **Accuracy of 0.78**. While acceptable, they are outperformed by the ensemble methods and the CNN.
6. **Tuned Random Forest**: Interestingly, the hyperparameter-tuned Random Forest Classifier (using `GridSearchCV`) achieved an Accuracy of 0.85, which is slightly lower than the base Random Forest model's 0.86. This could indicate that the default parameters were already quite good, or the tuning process did not significantly improve performance beyond a certain point for this specific dataset and metric.

Conclusion:

After successfully addressing data leakage, the **Random Forest Classifier (Base)** proved to be the best-performing model for classifying player auction prices into 'Low', 'Mid', and 'High Value' categories, with an **accuracy of 0.86**. The Bagging and Gradient Boosting classifiers also showed very strong and comparable results (0.85 accuracy). The goal of achieving 85-90% accuracy was met by the top-performing models. Further fine-tuning or exploring more advanced ensemble techniques for the top models might yield incremental improvements, but the current Random Forest model already provides a highly effective solution.

Summary:

Data Analysis Key Findings

- **Data Leakage Addressed**: The removal of the 'Auction Price Category' column from the features successfully eliminated the previously observed perfect model scores, confirming that data leakage
